If you like gum prints, but do not like the work connected therewith, or if you lack the time necessary, you can get the same effect quite easily by straight enlarging. Make an enlargement, getting it about three shades darker than you wish the picture to be. From this, by contact, make a paper negative. Soak this in a solution composed of eight parts of castor oil and two parts of ether. Incidentally, do not inhale too much of the ether, or the world may be deprived of the beautiful picture you are about to produce. And do not forget to keep the bottle tightly corked or the ether may go away and leave you. After soaking the paper negative in this, blot it, place between dry blotters, and use a hot iron until it is dry. Then make a contact print from your paper negative in the ordinary way, and you have what is, to all appearances, a gum print. I might add that this is the basis for the so-called "Qualitone" prints that I am making commercially from amateur negatives. To make them commercially practical, we have completely reversed the process, so that, as now used, the method would hardly suggest the parent idea. But just as the above process is impractical for commercial use, so is our method impractical when only a few prints are to be made, and therefore the outlined process is the one you will want to use.

To come back to bolting cloth for a moment. There are all sorts of possibilities in that material. You can put it on a stretcher and, by holding it in contact with the paper, while exposing, secure a delightful canvas or linen effect. By keeping the stretcher from a quarter of an inch to an inch away from the paper, you can get softness without losing detail or producing diffusion or fuzziness. Using the bolting cloth will necessitate about a third more than normal exposure. And be sure not to get cloth that has been folded or there will be a corresponding line in the picture. You can buy the cloth in rolls, glue it on the stretcher, and thus eliminate this difficulty.

Softness can also be secured by exposing through a lens cap made like the yellow one described, but covered with silk chiffon instead. While the chiffon is a department store commodity, it is well worth braving the peril attending its purchase, for it is very satisfactory as a softener. Still another method of softening the picture is to wave a piece of ground-glass or ground celluloid as close to the lens as you can during exposure, the ground side being towards the lens. If too much diffusion is thus secured, do it for only a part of the exposure.

To produce white borders on enlargements is a problem that has two solutions. You can either use a mask having an opening the size of the enlargement, using it against the paper, or mask the negative. The former produces a sharp edge which looks all right when the picture is sharp, but one that to me seems out of place and inartistic for a soft picture. It is somewhat more trouble to mask the negative exactly than it is to mask the enlargement; but I think that, in most cases, it is worth the trouble, for the softness so gained is in proportion and harmonious with the softness of the picture. Sometimes, though, when an excessively long exposure has to be given, you will get halation unless you use the larger mask in contact with the paper. To eliminate the sharp border objection noted above, you can use both, fitting the mask against the paper very accurately so that it will come about one-sixteenth of an inch outside the projected image all around. Frequently, of course, you will not care about the border, and then, naturally, it is a waste of time to mask the negative, it being only necessary to slip a mask over the paper. The other plan is suggested as being more artistic and satisfactory in most cases.

Now, before we go on, just a few words about vignetting. If you do not like the vignetting affair that is on sale, one that looks like an instrument formerly used for scaling fish, try some other method. The best known is to use a piece of cardboard somewhat larger than the enlargement being made, in which has been cut a hole of the general shape and about half the size of the desired vignette. By making the exposure through this, holding it about half-way between lens and paper, and moving it about to avoid a sharp edge, you can produce nice results. Or you can cut a hole in the cardboard about the size you want the vignette, pin it over your bolting cloth frame, and use it close to the paper—about half an inch away.

As to developers, you are pretty safe in sticking to what the manufacturer recommends. Any developer that gives good brilliancy and works with average speed will do. Bromide enlarging requires slow and full development for best results. The proper use of potassium bromide is very important in enlarging—more so, I think, than in printing, where it does not matter so much what tone results. Under-exposure and forced development are less disastrous than the reverse. If a print refuses to come up with proper brilliancy, you can sometimes "snap it up" a little by adding to every five ounces of the normal elon-hydroquinone developer, the following solution:

Bromide of potassium, saturated solution ...	6 drops
Nitric acid, C.P.	2 drops
Prussiate of potash, red.....	3 grains

There is another way to "snap up" a developer, but I hesitate somewhat in telling it, for I know you will say, "Heavens! Did they bring that man five hundred miles to tell us to put hypo in the developer?" But I will bravely suggest that, when a print positive refuses to come up with the desired snap and brilliancy, you add, as a last resource before giving it up, one drop of a 25 per cent. solution of hypo to each ten ounces of developer. A friend of mine to whom I made this suggestion understood me to say one ounce. He hardly got the results he expected.

Local development, or the hastening of development in some one part of the picture, can be used, in connection with shading and dodging in exposure, to correct uneven densities in the negative. The best way I have ever employed, and one I have never seen described in print, is: Take a bottle and fill it with undiluted stock developing solution, and, instead of a cork, use a wad of cotton in the neck. Then, during development, simply hold the bottle upside down and rub that portion of the image it is desired to strengthen, while the rest goes on normally. This has the advantage over local rubbing, heating, and the like methods, in that there is no danger of staining, since the print is kept fully immersed in the developer during the entire process. Still another plan is to blow upon the desired part through a tube, and thereby keep a current of air upon the portion it is desired to speed up. This last is particularly useful in building up small places, while the bottle with the cotton stopper is more useful for large areas.

A good little "stunt" that is most effective, particularly when making small enlargements, where it is difficult to shade evenly, is this: Put the paper in an ordinary printing frame behind a sheet of ground-glass facing out—that is, with the ground surface away from the paper. You can use celluloid with a ground surface by placing a sheet of clear glass between it and the paper. Put the frame in position on the enlarging easel, and focus. With the focussed image projected through the yellow cap, dab a little vaseline on the ground-glass at places where more exposure is wanted. Rub it in well to get it even, and expose. The vaseline makes the ground-glass transparent while the ungreased parts hold back the light. Similarly, you can hold back certain parts still more, if neces-

ary, by rubbing finely powdered green chalk on the ground-glass surface directly over them.

I have a suggestion or two to make regarding re-development that may be worth the time required to mention them. In the first place, by lessening the amount of bromide in the original developer you can to a great extent eliminate the disagreeable tone of yellow in the sepia. Or if you are making black and whites at the time, and cannot therefore cut down the bromide below normal, try soaking the print in the sulphide solution of the re-developer before bleaching. In fact, I believe that the latter plan is, after all, better than varying the bromide in the developer. I can positively guarantee, if you will soak the print three minutes in the re-developer (sulphide bath) before bleaching it, that not only will you get a beautiful chocolate brown, with no trace of yellow, but that the density of the sepia print will be exactly the same as the black and white. These two advantages are rather big ones, and well worth while.

Do you occasionally get blue spots in the paper after sulphiding? Try adding a little oxalic acid and oxalate of potash to the sulphide solution. It doesn't always work, but oftentimes will save a picture. A fresh sulphide solution occasionally eliminates the trouble. And here is another "stunt" that may be worth while. To produce pictures that are part sepia and part black and white, get a ten or fifteen cent tube of what is called "Jiffy Solution," used for mending bicycle tyres, and pour some of this over the parts you want to remain black and white during re-development. It dries quickly and is easily peeled off after the print has been redeveloped in the usual way. With a little judgment you can use this solution to produce some delightful effects—warm toned faces and arms with cool toned drapery; warm sunlight splashes with cool-looking shadows, and so on. A plain colloidion, such as the druggists sell, might answer as well or better; I have not tried it.

Now, a few miscellaneous hints that may be of use to you, and I am through. To remove a scratch on the glass side of a negative, make a fine thick paste of emery powder and water, apply with a piece of flannel and rub until the edges of the scratch are literally cut off. The scratch will not show in the print, and this is quicker than spotting, particularly if a lot of prints are to be made from one negative.

To hold back faces and other small areas that print too dark, two methods are applicable. Use a piece of cardboard on the end of a wire—a hat-pin is good—taking care to move the wire sufficiently to avoid its making a light streak on the print. If the exposure is not long enough to permit enough of this dodging without it showing on the print, stop down. And speaking of stopping down, quite often you can increase contrast by stopping down judiciously. As a rule, however, in

enlarging, a stop about $f/16$ is ideal; and I think we are safe in saying that an exposure of not less than fifteen seconds is desirable. The longer the exposure required, the better for the picture, if you have the patience.

The other method consists of using a narrow strip of glass with a spot of opaque on one end. This is somewhat better than the cardboard and wire method, for it cannot produce a white line if you neglect the moving, as the exposure goes on right through the glass.

Double printing should not be overlooked, as enlarging offers the widest possible field for its application. And here is where the yellow cap is again indispensable. Put the negative in place, with yellow cap on lens and paper in position. Then fit up a strip of cardboard to shade the sky portion, fastening it a little away from the paper so that there will be a soft, vignetted edge to the landscape, not a sharp outline. Mark where the sky line comes at the two sides of the picture, make the exposure and remove the negative. With the yellow cap again in position, the exposure having been made by removing it, locate the clouds just right on the paper, using the pencil marks at the sides as a guide. Move the masking cardboard to the other side to shade the part already exposed, and print in the clouds.

To get a negative which, when exposed in contact with the picture negative, will give a canvas effect: Get a piece of hair-cloth from the tailor, set it up so that the light strikes across it from one side, and photograph it, developing for contrast. A quick-acting reducer will sometimes improve such a negative and prevent its making the exposure too long when in use.

Occasionally you will want to make a particularly nice-looking job of enlarging one figure from a group, and here is a good method of procedure. Make a regular enlargement from the group negative, place it in an ordinary printing frame with a sheet of clear glass in front and the picture side of the print towards the glass. Mix opaque and whiting until you have a very light gray substance. Paint this all over the glass around the figure you want to separate from the group, just as you would were you blocking out a negative. Next put a deposit of soot all over the glass, opaque and all, by holding it over a kerosene lamp. Carefully wipe away the soot from the clear glass over the figure, and then work in some shading or design around this clear space by wiping off the soot so as to leave the gray opaque showing through in places. After you have a nice background design worked in, copy the whole thing through a sheet of glass. Have a piece of black cloth, with a hole cut in it for the lens, suspended in front of the camera in order to prevent reflections from the glass. The result will be a nice negative of the desired figure, with a tapestry effect background; that is, if your work with the gray opaque and the soot was well done.

FRANK B. HOWE.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography.
Hon. sec., 5a, Pall Mall East, London, W.C.1.

October 13 to November 29.—Royal Photographic Society.—
Entries close September 19 (carrier), September 20 (hand).
Secretary, J. McIntosh, 35, Russell Square, W.C.1.

THE BARN COMPETITION, promoted by Elliott and Sons, Ltd., manufacturers of Barnet plates and papers, closed on August 30, and has proved a very interesting competition. It has revealed a wonderful assortment of barns up and down the country, many quaint buildings, some picturesque and affording delightful studies, other historical and notable. The large entry showed that the idea was thoroughly appreciated. The standard of work was very good. The successful competitors were Walter North, 159, Portland Road, Hucknall, first prize, £5; R. W. T. Collins, Woodlyn, Shakespeare

Road, Worthing, second prize, £3; J. Stewart, 60, Cromer Street Clifton, York, third prize, £1.

POLYTECHNIC PHOTOGRAPHIC SCHOOL.—We have just received a prospectus of evening classes which will be held at the Regent Street Polytechnic, London, W., during the coming season, commencing on September 29. There are classes on General Photography, Studio Portraiture, Black and White and Colour Finishing, Advertisement Figure Portraiture and Finishing, Retouching, Enlarging, Science for Photographers, Cinematography, Commercial Photography, and Catalogue Work, Tone and Three-colour Process Work. The classes in each subject are held from 7 to 9 p.m. Full particulars will be forwarded upon application to the Photographic School, and the teachers will be present on the evenings of the week September 22—26, from 6.30 to 9 p.m., to enrol and advise intending students. We may add that each subject is dealt with by a specialist with commercial experience in his particular branch.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).

Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).

MINIATURES.

We generally find upon a photographer's card or letter paper the word "Miniatures," but in most cases these little pictures play a very small part as moneymakers in the business. This is, I think, largely due to insufficient thought being given to their production, and also to a lack of salesmanship on the part of the receptionist. Where a photographer "lays himself out" to produce miniatures of a high grade he usually finds it highly remunerative, and retains in his own hands business which is so often allowed to drift away to outsiders, by which I mean jewellers and fancy dealers who sell locketts, frames, and cases, and exhibit miniatures as a side line. As in many other branches of photography, it is a mistake to show very cheap work unless it is asked for, and in a studio of any pretensions the stock frame of gilt or rolled gold rims and pendants filled with roughly tinted P.O.P. or bromide prints should never appear, although they are, of course, quite in place in a working class district, or in places where the business consists mainly of postcards.

The miniature, properly so called, is a small water-colour painting direct upon ivory, and as such work calls for a high degree of artistic skill it is necessarily rather costly. There is, nevertheless, quite a good market for these, and I have taken many orders at prices ranging from five to twenty-five guineas for each picture, including a best-quality rim, or, if preferred, a leather case. If one is provided with a few good specimens it is easy to point out the superior transparency and purity of colour of a free-hand miniature, as compared with one on a photographic basis, and also to emphasise the ease with which alterations in dress, or even the features, can be made, while the undoubted permanency of the work is another good selling point. One common error must be avoided, and that is to endeavour to cheapen the production for the sake of extra profit. I have known unscrupulous photographers to offer the artist as little as two guineas for a painting for which the customer has paid ten. This is sheer profiteering, and in the end is bad business. I consider that the artist should receive at least half the selling price, leaving the balance to cover cost of mounting and profit.

To come to the photographic part of the business, the best class of miniatures are painted upon a faint carbon image supported upon ivory. These require less skilled artistic work, and any fairly good colourist can finish them, although a trained

miniature painter will usually produce a more satisfactory result. The photographer, if a skilful carbon printer, can easily produce the plain print on ivory, but as a general rule it will be better and cheaper to give the job to a good firm of carbon printers. It is desirable to consult the artist as to the colour of the tissue to be used, as some prefer to work upon a warm toned basis, while others prefer a cold toned one. Sepia, standard brown, and warm black are the most useful colours. A little consideration should be given to the natural colouring of the subject in settling which should be used, as it is much easier to paint fair hair over a warm basis and dark hair over a colder one. As a fair price can be obtained, the greatest care in the selection of the colours used should be exercised, only those of undoubted permanency being employed. Books on miniature painting which deal fully with this question may be obtained for a shilling or so from most artists' colourmen.

A still cheaper class of work is produced in exactly the same way upon celluloid instead of ivory, but I do not recommend the use of this material, as the saving in cost is slight, perhaps half a crown on a two-inch picture, which is hardly worth considering unless the selling price is less than a couple of guineas. Naturally a cheaper quality of colouring is put upon this material.

For small framed pictures opal glass is often used as a basis for the photograph, but does not give the same effect as ivory or celluloid, and is better suited for C.D.V.s and larger sizes. It is very suitable for small highly finished monochromes on red chalk or sepia, and a few specimens in this style may bring orders from those who do not care for coloured pictures.

Before dealing with paper pictures, I must mention the Transferotype paper of Kodak, Ltd., which allows a bromide print to be transferred from its original support to ivory, celluloid or porcelain. As it in no way differs from an ordinary bromide image it is not comparable either in the matter of transparency of image or of permanence with carbon, but is nevertheless useful when these qualities are not in the highest degree essential. The process is very simple, being exactly similar to ordinary bromide printing up to the point of transferring, which is very simply done by soaking the finished print in water until it is limp, when it is squeezed down upon the final support and placed under light pressure for about an hour. It is then immersed in water as warm as can comfortably be

borne by the hand, when the paper can be lifted off, leaving the film upon the support. A good rinsing in the warm water is given to remove the surplus gelatine substratum, and the process is complete. The image can be sepia-toned in the ordinary way before or after transferring. It must be remembered that the image is reversed in the transferring, so that if this be objectionable the print must be made by means of the camera or enlarging apparatus. I have found this very convenient when small prints are required from larger negatives, as the reduction and reversal can be made simultaneously by placing the glass side of the negative next to the lens. The paper is obtainable in the usual sizes at the same price as ordinary bromide paper, and full working instructions are given.

Very effective quasi-miniatures may be made by colouring platinotype prints with water colours. The effect is excellent, and they are, of course, quite permanent. I have one example which was produced over twenty years ago, which so far as I can see has not changed in the slightest degree, in spite of storage for some years in a very damp place, where ordinary P.O.P. and bromide prints had almost entirely faded away. Carbon prints can, of course, be treated in the same way, and are equally effective.

I would strongly advise that in all cases genuine artists' colours should be used in preference to dyes, even for the cheaper class of work. Some dyes are permanent, but there is no means of ascertaining which are, so that, except for the "eighteenpenny touch," they are best avoided. One has only to look at the specimens in the jewellers' windows to see how fugitive most of the colours are, especially the reds and pinks, and these, naturally, are the most important. Dyes which are fairly permanent when used alone often form fugitive mixtures. I well remember finishing a landscape with a mixture of dyes which gave exactly the brown colours I wanted. In three weeks it came back, a clump of brown trees having turned to a bright green!

Our miniatures should be fitted up in rims or frames in accordance with their value. In some few instances solid gold rims are ordered, but the majority of best quality rims are made by hand of fine copper, which is heavily gilded after being made; if carefully used these will retain their brilliancy for many years. They should be enclosed in a morocco snap case, lined with silk, and care should be taken that the colour of the lining does not detract from the picture. For this reason I always specify white or cream for light pictures, and very dark colours for dark ones. Dark green, blue, or brown may be used, whichever will best harmonise with the prevailing colour of the painting. The glasses must be absolutely colourless, as the slightest tinge of green is fatal to delicate colouring.

The fitting of an ivory picture into its rim is rather a delicate operation if it has to be cut into an oval or circle, as it is very easy to split the ivory by cutting against the grain. Supposing that we have an oblong ivory to cut into an oval rim, we must take a small sharp pair of scissors and commence by cutting from the middle of the right hand side round the edge of the oval to the top; the margin will probably split off in pieces. We then turn the ivory over so that we are looking at the back. This brings the other top corner into position for cutting, which we do in the same way, the two cuts meeting at the top. The two bottom corners are cut by turning the picture upside down and proceeding in the same way. It is worth practising this on a piece of plain ivory before risking a valuable painting.

Enamel miniatures, those which are burnt in upon copper or porcelain, are, of course, beyond the powers of most photographers, and must be placed in the hands of a firm which specialises in this class of work. Unless the enameller also supplies the rim, it is advisable that this should not be ordered until the picture is delivered so as to ensure a proper fit, as such pictures can only be cut with great risk of damage.

Miniatures are sometimes required on watch dials or inside the cases or domes. They may be either ordinary coloured carbon prints or enamels, but in either case the portion which is to receive the print should be detached by a watchmaker to avoid damaging the works. Carbon prints transferred to matt-surface silver look very well, but gold should either be silver-plated or given a coat of white enamel similar to that on the dial. The carbon image can then be put on by the ordinary double transfer process, a preliminary substratum of insoluble gelatine being necessary. A coating of celluloid varnish or amber dissolved in chloroform is advisable to protect the gelatine as no glass covering is possible. Enamels require no protection.

PRACTICUS.

SULPHIDE TONING WITH POLYSULPHIDE.

In the current issue of the "Bulletin of the French Photographic Society" M. L. P. Clerc has a note on the process of sepia toning with polysulphide, originated some years ago by M. Desalme, a translation of whose communication appeared at the time in the "British Journal" of February 28, 1913, p. 157. M. Desalme's method consisted in making a solution of polysulphide by boiling sulphur with strong solution of ordinary sodium sulphide, or by mixing a strong solution of sodium sulphide with hydrogen peroxide. The yellow solution produced in each case is largely diluted with water to form the toning bath, in which prints gradually tone from a black to a warm sepia ground in about thirty minutes.

M. Clerc has found that the process does not work with the same readiness in the case of all papers, and that certain brands refuse to tone at all. The simplicity and cheapness of the process and the excellent results obtained under suitable conditions have therefore prompted him to make tests of a number of prints which showed no toning action after an hour's immersion in the bath with the object of discovering the cause of their failure to tone.

In order to test the condition of the image of a print which had thus remained untoned in the polysulphide bath, a print was well washed and treated with Farmer's reducer. The image was slightly reduced at the same time, becoming, almost instantaneously, of sepia tone. It thus seemed that the particles of reduced silver were attacked superficially in the hypo-ferricyanide bath, a layer of black metallic silver being removed from the nucleus of brown silver sulphide, and disclosing the toning already partly completed. In these conditions it appeared probable that toning would take place by prolonging the time of immersion of the prints in the polysulphide bath for a sufficient time.

The strength of the solution appeared to have no influence either on the time of toning or the colour of the prints. The only practical means for increasing the speed of toning thus appeared to be the use of a higher temperature. Prints which had been toned for one hour without having exhibited any change were hardened, with other untoned prints, in weak solution of formaline, and then immersed in solutions of polysulphide at various temperatures. Toning was found to take place more rapidly according to the temperature of the bath. At a temperature of about 120 deg. F. toning was complete in ten minutes, but the tone was no longer sepia brown, as when toning in the cold, but purplish brown, resembling the tone obtained by hot hypo-alum.

Other prints which refused to tone in the cold within a reasonable time were kept in the polysulphide solution for a longer period than two hours. With two hours' immersion at a temperature of about 60 deg. F. the prints became warm black; after three hours some of them toned to a very pleasant purplish brown, whilst others took six hours to tone to sepia brown.

The same process of toning is applicable to glass transparencies, the toned images being much more transparent than before toning. In testing the action of the bath on transparencies made on different brands of plate, the same differences are met with as among papers. Some transparencies tone rapidly whilst others are difficult to tone, and show an alteration of colour only after several hours' treatment. Still others obstinately refuse to tone even after very prolonged immersion in a heated bath.

The differences here noted by M. Clerc conform fairly closely to those which are found in the case of the toning of bromide papers with liver of sulphur. It is no doubt common knowledge that some

bromide papers tone very readily by this method and yield excellent results, whilst prints on other papers seem almost untenable in a "liver" bath, although both descriptions of paper will tone with equal readiness both by the bleach and sulphide method and by hypo-alum.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Labelling Bottles.

The usual paper label, as all are aware, is rather a delusion and a snare, owing to a tendency to drop off, and perhaps is swept up unnoticed, often leaving one in a state of doubt as to the contents of its divorced companion.

A plan which has been found good consists in using very thick gum to which a few drops of a saturated solution of potassium bichromate have been added, just sufficient to turn the gum orange. The mixture will not keep. On exposure to light the gum is rendered insoluble, or partially so. When dry, the label, which should be of good quality paper, is coated with celluloid varnish, working it a little above the label. Labels so affixed have remained *in situ* for years, though continually exposed to damp. They have also withstood occasional rinses under the tap to remove attached crystals due to solutions trickling down the bottles after pouring.

A label which never drops off is made by applying lettering in anti-sulphuric paint direct to the glass. It will withstand nearly all chemicals, is unaffected by water, and adheres with tenacity, being vastly superior in these respects to ordinary paint, Berlin black, shellac varnish compounds, etc. Capital also for making plainly visible the numbers and graduations of clear-glass measures, frequently difficult to read in the dark-room. The anti-sulphuric paint or varnish is supplied in black and red by electrical houses, and although expensive, a little goes a long way. It has many useful photographic applications—touching up old *papier maché* dishes, rendering wood waterproof, painting metal plate-washers, and the like. It dries rather slowly, and should not be applied in thick coats, and care must be taken that no tears form, as these take a long time to set.—CHLORIDE.

Photo-Mechanical Notes.

Avoiding Moire Pattern.

Nothing is so annoying to the half-tone engraver as the unpleasant pattern that is bound to occur when the lines of a copy meet the lines of the screen at too narrow an angle. The first thing the operator does is to twist the original, or revolve his screen until he gets the least obvious pattern, and sometimes this is all that is necessary to do to cause it to entirely disappear. But some subjects are not amenable to this treatment; for example, in a subject having circular lines the pattern is bound to occur no matter how you turn original or screen. An irregular grain screen is a good solution of the problem, but sometimes the customer objects to an irregular grain, and frequently the engraver has not a suitable irregular grain screen. In the case of the circular lines, after the half-tone is made it can be tooled by the engraver to make the pattern almost disappear. Another instance of the pattern being dodged very neatly is that of the engraver who had to reproduce some steel engravings. He twisted them until the pattern was at its minimum, and was at only one spot. This position was carefully marked, the original was then lightly air-brushed so that the lines were just obliterated, of course keeping the tone of the subject the same. Then the engraving was made, and the hand engraver imitated the lines of the original on the patch which had been air-brushed and reproduced as an even tone, thus very successfully avoiding the uncomfortable moiré pattern.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, Sept. 1 to 6.

CINEMATOGRAPHY.—No. 21,987. Cinematograph apparatus. A. S. Newman.

CINEMATOGRAPHY.—No. 21,780. Spools for cinematograph films. R. Rigby.

PROJECTION LANTERN.—No. 21,507. Projection lantern for advertising. C. E. Dyte.

PROJECTION SCREENS.—No. 21,452. Daylight cinematograph screens. W. J. Marks.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ROLL-FILM CAMERAS.—No. 128,637 (August 20, 1917). The invention relates to an automatic roll-film camera for taking pictures of successive portions of an object or landscape from a moving vehicle, such as an aeroplane. The drawing shows a transverse vertical section. The shutter 32 consists of an endless curtain having two apertures and moved intermittently transversely of the film, which passes between the upper and lower portions of the shutter.

The take-up spool 11 is of such a size that each lap of film around its core will constitute an integral number of pictures or a single picture, and is provided with one or more notches to indicate where the film should be cut to sever the separate pictures.

The shutter and film are alternately moved by continuous rotation of a shaft 21 from a spring 22. This shaft carries a mutilated

gear-wheel 24 engaging with a mutilated pinion 27 on the spindle of the take-up spool; it also operates bevel-gear 40 . . 43 and spur gear 46, 49, 47, the wheel 47 being loosely mounted on a shaft 48 which is intermittently rotated by a spring wound up by the wheel 47 which movement is transmitted to the shutter by gear 51, 52. The movement is regulated by a dash-pot comprising a piston 63 operated by screw-and-nut gear and working in a cylinder 58. The operation of the camera may be stopped by screwing down a needle valve 68. H. G. C. Fairweather, 65, Chancery Lane, for G.E.M. Engineering Co., 1,216, Walnut Street, Philadelphia, U.S.A.

FOCAL-PLANE SHUTTERS.—No. 129,037 (October 2, 1917). The invention relates to focal-plane shutters such as those described in Patent No 6,258, 1912 (B.J., April 25, 1913). Means are provided for holding the winding-handle C in gear during the setting

of the shutter, and for holding it out of gear at other times. When the handle C is rotated, a bevelled surface c' on a shoulder c'' comes into contact with one end of a slot formed in flanges f , g , and the handle is thus forced inwards against the action of

a spring E until a clutch member on the end of a sleeve D engages a pin b' on the shaft b of the setting-mechanism, and the shoulder continues to travel under the flange until it engages a stop f' . The flange g is rotatable relatively to the flange f to vary the size of the slot. Thornton-Pickard Manufacturing Co., A. G. Pickard and F. Singer, all of Altrincham, Cheshire.

FLASH LAMPS.—No. 122,719 (February 12, 1918). The invention consists in a device for producing flashes by the electric volatilization of fusible wires, for instance of aluminium, copper, or magnesium. It comprises an insulating support with eyelets for attachment of the wires, another support for conductive plugs engaging the eyelets, and a current distributor allowing a variable number of wires to be volatilized at each operation. In one arrangement, the wires C, Fig. 4, connect a circular row of eyelets B in a cardboard disc A to a central eyelet. Plugs E, which may be spring urged, are mounted on an insulating base D and enter the outer eyelets B, while a pin G inserted through a central eyelet into a

Fig. 4.

socket H in the base presses the disc A towards the base. The socket H is directly attached to one conductor, and the plugs E are connected to a row of contacts M, Fig. 5, on a plate I. A switch arm J carrying a brush N is held by a catch P, which can be disengaged by a Bowden wire U. A spring L then rotates the switch arm, which sweeps over the contacts M until a stud T on the switch arm meets a stop arm Q, retained in the desired position by a pin R inserted in one of a number of holes S. In another arrangement, the wires are in series between eyelets b , Fig. 9, in a flexible band a , which in being wound off a drum W on to a drum W' passes over a wheel i carrying studs e . These studs engage the eyelets and are attached to contacts m successively engaging a pair of brushes n, n' . A pinion X on the wheel i gears with a toothed wheel Y which is driven by a spring l wound by a chain o and connected to the wheel Y by a ratchet-wheel and pawl r' . A catch y'' acting on the ratchet-wheel can be withdrawn electromagnetically.

The amount of rotation and consequently the number of wires volatilized is determined by one or other of two wheels Z, Z'' geared to the ratchet-wheel, the wheel Z rotating more slowly and the wheel Z'' rotating more quickly than the ratchet-wheel. A pin t or t' on either wheel is arrested after the required movement by an arm q or q' secured by a pin r or r' entering holes in an arc V or V' . The arm q or q' not in use is folded up out of the

way about a hinge z or z' . A fixed stop arrests the pin t in zero position when the spring is wound up.

To use more wires than allowed by the wheel Z, both arms are thrown out of action; still more wires can be burnt by turning the drum W' by hand. In another arrangement, the contact wheel

Fig. 9.

Fig. 5.

is driven by a belt from a crank-actuated shaft on which is a cam periodically closing a switch connected to the brushes. In another arrangement, the wires are transversely or diagonally arranged on the band, and the pairs of eyelets are engaged by studs on a drum having on its ends contacts connected to the studs. A further modification consists in winding the wire continuously around an asbestos or like band and attaching it at intervals to eyelets. —J. and P. Courtier, 20, Rue Ernest Cresson, Paris.

New Books.

KELLY'S DIRECTORY OF THE CHEMICAL INDUSTRIES, 1919.—The expansion of chemical industry in this country is marked by the larger size of the latest edition of the directory of the trades just issued by Messrs. Kelly's Directories, Ltd., 182, High Holborn, London, W.C.1, which runs to nearly 880 pages, as compared with 809 pages of the previous edition, issued in 1916. Part of the increase is, however, due to rearrangement of sections. The compilation is chiefly of interest to those in the photographic trade, or to anyone having dealings with photographers and photographic dealers, from the information it gives on the distribution of these two classes of traders. In the classification of trades and professions, divided into two sections, namely, London and Provinces, photographers and photographic material dealers are among the largest lists. The earlier portion of the book consists of an alphabetical arrangement of places under the counties of England, Scotland, and Ireland, and thus shows the name of a photographer or photographic dealer in a given town. As we have pointed out in the case of previous editions, the particulars given of manufacturers of dry-plates, printing papers, photographic apparatus, and photographic chemicals are wanting in accuracy, chiefly as the result of insufficient discrimination between actual manufacturers and merchants; and in one or two cases we notice makers of sensitive materials figuring rather strangely as manufacturers of apparatus. These, however, are minor defects, which are almost immaterial in their effect upon the great usefulness of a very valuable compilation.

STEREOSCOPIC PHOTOGRAPHY.—For some years past there has not been a text-book of stereoscopic photography in print. The want has been remedied by the publication of No. 175 of the "Photo

Miniature," just issued in this country by Messrs. Houghtons, Ltd., 38-39, High Holborn, London, W.C.1, and in America by the publishers, Messrs. Tennant and Ward, 103, Park Avenue, New York. It is a comprehensive and brightly-written little manual, which touches sufficiently upon the historical details of binocular vision and stereoscopic photography, and deals at length with the practical methods of the latter of the ordinary kind, and also of such special applications as the making of X-ray stereograms and of stereoscopic colour transparencies on the Autochrome and Paget plates. The manual may be commended to the amateur photographic worker as an excellent guide in these branches of work.

CHEMICAL REAGENTS.—A re-edition of the work by Dr. C. Krauch, chemist, to the firm of E. Merck, has been issued by Messrs. Scott, Greenwood and Son, 8, Broadway, Ludgate Hill, E.C.4, in the form of a revised and enlarged translation by H. B. Stocks, F.I.C. This is a translation from the third German edition, and very largely extends and supplements the first English edition published seventeen years ago. The arrangement throughout is alphabetical, but the text is rendered still further accessible by the inclusion of an excellent index. In the case of each chemical reagent indications are given of the commonly occurring impurities, together with specific tests for their detection. In each case also the paragraph mentions the uses of the reagents, and in doing so cites abundant references to original papers in chemical literature. The translator has rendered a very great service to the English reader by making these references, whenever possible, to English chemical journals in which the same matter has appeared. The book, which has long been a standard treatise on its subject, is one which is invaluable to the experimental chemist. Its price is 17s. 6d.

New Materials, &c.

Metol-Griffins and Amidol-Griffins. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.2.

METOL and amidol of British manufacture are two new introductions of Messrs. Griffins which will be found to deserve the good opinion attaching to these popular developers. Made up according to the customary formula of sulphite and a little bromide the amidol yields prints of the brilliance and fine black colour characteristic of this developer. The metol, employed in an ordinary developing formula in conjunction with hydroquinone shows itself as possessing the qualities which have brought this combination into universal use for both plates and prints. Although the developers are not as free from colour as other products, yet the difference appears to have no effect upon their developing properties. They are sold at the following prices:—Metol 72s. per lb., 4s. 6d. per oz; amidol 32s. per lb., 2s. per oz.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Hackney Photographic Society. Print Competition: Pictures, including a portion of St. Paul's.

THURSDAY, SEPTEMBER 25.

Hammersmith (Hampshire House) Photographic Society. "Egypt." A. Keighley.

CROYDON CAMERA CLUB.

Mr. J. W. PURKIS gave another contribution to the informal session with an elaborate exposition on copying appliances of the "Hectograph" order, a most useful contribution for secretaries and all who have to do manifolding. He gave various formulas and tips, of which only those found best need be recorded.

The best formula for the jelly, which possesses advantages over the commercial article, he had found to be as follows:—

Leaf gelatine	1 part by weight.
Water	5 parts by measure.
Golden syrup	8 parts by "
Carbolic acid, 10 per cent. solution . . .	1-16 part by "

Break the leaf gelatine into small pieces, and soak in the water for about 30 minutes. Heat in a water bath till dissolved; add the

golden syrup and preservative; filter through fabric into a shallow dish, and skim off scum with the edge of a piece of clean paper. For a 10 x 8 dish about 2½ ozs. of the gelatine, and other ingredients in proportion, will be about right. If to be consumed as a jujube, omit the carbolic. In either case, use when set.

The ordinary commercial graph inks answer well. For home-made ones he had no formula, adding to a saturated solution of methyl violet sufficient sugar to make the ink flow easily. Fountain and stylo pens may be employed with fair success, but being designed for thin inks do not respond kindly to thick. Specially designed pens for thick inks might be made. With a stylo, enlarging the hole and reducing the diameter of the pin would do all that was necessary.

Copying-pencils are effective, but only applicable to "Hectograph" flexible gelatinized copying sheets. He had tried many pencils with varying success, and could recommend the "Eagle Manifold" which renders 50 legible copies. A rough paper for the original is necessary. Better, a non-absorbent material such as acid-etched ground-glass. "How would a carpenter's rasp do?" enquired Mr. Sellors. "Too severe," said the demonstrator. Care must be taken to secure good contact all over the surface of the jelly. He left the ground-glass in contact for 15 minutes and upwards. Possibly a shorter time would answer, but as the secretary had advanced his demonstration a fortnight he had not had time to try.

He then gave a practical demonstration of the making of the jelly, using an ingenious water bath consisting of a saucepan containing a jam pot supported on fireclay tops of worn-out inverted incandescent gas burners, capital appliances for the purpose. It was noticed that as he poured the Lyles syrup it seemed strangely thin, and this was pointed out. "Quite true," he said, "but for the purpose of this demonstration I had to add water to eke out the stuff, for I dared not sneak another tin." "Married, of course," remarked the "office boy" in pitying accents. A most hearty vote of thanks was accorded Mr. Purkis for a very complete demonstration.

During the evening the secretary, Mr. Sellors, announced that he was going to indulge in a month's holiday. The assistant secretary (otherwise the "office boy") would act in his absence. Any incivility or inattention should be immediately reported.

Commercial & Legal Intelligence.

PHOTOGRAPHIC ENTERPRISES.—At the London Bankruptcy Court last week, before Mr. Registrar Francke, the public examination was held of Frank Soward, 32, Coniston Road, Muswell Hill.

According to the debtor's amended statement of affairs the gross liabilities were estimated at £819 13s. 1d., of which £660 13s. 1d. was expected to rank against the estate for dividend, and assets nil, thus showing a deficiency of £660 13s. 1d.

In reply to questions put by the Official Receiver, debtor stated that he was introduced to a certain person, who told him there was a good thing going in "Colourgraphs, Ltd." Debtor and several friends, in about December, 1917, purchased 600 or 700 shares at par, of which debtor had fifty. Their informant was introduced to debtor as manager of Colourgraphs, Ltd., and he suggested promoting a new company to be styled Photocol, Ltd., for the purpose of taking over the assets and undertaking of the old company, obtaining capital for the working of the secret process it held relating to the enlargement and colouring of photographs, and the securing of premises at Thornton Heath. Debtor was asked if he could find some capital for these objects. He approached three of his friends, and they found £400, which debtor paid to his informant with moneys of his own. Altogether debtor had paid in this way about £1,100. Debtor was to receive 1,000 fully paid shares of £1 each in Photocol, Ltd. No part of the advances made by debtor to the payee had been repaid, neither has he received any shares in Photocol, Ltd., which company is still in existence and did not recognise the payee. Debtor estimates his loss in connection with this venture at £1,100, less the value of 1,500 shares in Colourgraphs, Ltd., valued at £150.

Debtor now submitted a proposal for the payment of a composition of 5s. in the £ to his creditors.

The examination was concluded.

EYEGLASS FOCUSING MAGNIFIERS.

To the Editors.

Gentlemen,—Will "Bi-focal" please explain how he gets binocular vision with a pair of eyeglasses fitted with magnifying lenses to fit the wearer's sight. Any magnifier with a longer focus than 3 in. is hardly worth while. If such eyeglasses working at this distance could be made to give binocular vision it would be a blessing in many ways. Probably their least use would be in focussing, for binocular vision is not necessary for this purpose. If both hands must be free, what is the matter with a watchmaker's eyeglass? It is cheap, and when a ground-glass screen is used nothing more is necessary.

May I remind him that the inventor of bi-focal died 130 years ago?

—Yours truly,

TRAVERS J. BRIANT.

Beverly, Epsom, Sept. 14, 1919

Gentlemen,—I read "Bi-focal" today with interest. Focussing is my trouble. I use the usual form which touches the ground glass, and have fitted a spectacle glass on top and take off my two-lens spectacles. With the lower glass I can easily read and write, but not focus with them on a ground glass. Hence the magnifier, which is only of local use, and I often find a falling off in other parts.

I can see it is possible that the same power of this focussing lens can be fitted into the lower half of a spectacle frame. If so, why have I and hundreds of others getting into old age been working with this one-eye difficulty, when two could be had, and the means provided of a quicker and general all-over survey which you feel the want of when focussing in portraiture. Do you consider this so-called Franklin lens is possible, and are they reasonable in price, and where should one go?—Yours, etc., T. C.

In answer to the above "Bi-focal" writes:—I find the bottom lenses of my bi-focal eyeglasses are something under 3-in. focus, but they are getting a little too long, and I must have a new pair fitted of shorter focus. It may not be quite correct to call them magnifiers, but they have proved very useful for ten years or more, if occasionally changed for a stronger pair, and enable me to focus in comfort, and if I require more magnifying power I can use the ordinary eye-piece magnifier. Will Mr. Travers J. Briant kindly explain how I am to fix a watchmaker's eyeglass on my eye when I already wear eyeglasses for astigmatism?

It is those who, like myself, are getting into the "sere and yellow" that will, I think, find my suggestion of value. Those who are fortunate enough still to possess the youthful power of "accommodation" can afford to despise it. The date of the death of the inventor of bi-focals does not interest me, although I am grateful to him for his invention.

"T. C." will find the bi-focal lenses of shorter focus quite reasonable in price, to be obtained of any good optician, and he need only explain the purpose for which they are required.

AN AEROPLANE WORKS CAMERA CLUB.—A photographic society, to be known as the British and Colonial Camera Club, has been established by the staff of the British and Colonial Aeroplane Company, Ltd., Filton, Bristol, and has its own little organ in the magazine, "The Bristol 'Bullet' in," issued by and for the employees of the firm. The president of the club is Mr. T. Temple Robins and the secretary Mr. F. Broad, whose address is c.o. The British and Colonial Aeroplane Company.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. B.—Generally speaking, we are of opinion that prints toned with liver of sulphur are not altogether as permanent as those treated by the customary bleach and sulphide baths. With liver, according to any formula, you tone only part of the silver image, whereas by the double bath process you convert the lot into silver sulphide, which is a highly permanent compound.

C. N.—Autochrome plates can be got by putting your name on a waiting list. We believe the Paget plates can be supplied. Sulphuric acid is by no means as good a preservative of pyro as metabisulphite, but there is no other disadvantage in using it, except that if it is used in any considerable proportion allowance must be made for its neutralising the alkaline solution of the developer.

C. S.—Individuals suffer as the result of being unduly sensitive, and developer which will be quite innocuous to one person is virulent in its effects upon another. The only developer for bromide papers which is quite free from these dangers is ferrous oxalate, the old iron developer. Used with due observance of the washing in weak acid between development and fixing, it is absolutely as fine a developer as there is for bromide paper.

A. AND A.—The only book on the iron printing photo copying processes, which is now in print, is "Photographic Reproduction Processes," by P. Duchochois, published by Messrs. Hampton and Co., Cursitor Street, London, E.C., price 2s. 6d. Another manual, "Ferric and Heliographic Processes," has been out of print for some years, but perhaps might be bought from dealers in second-hand books, such as Messrs. W. and G. Foyle, 121-123, Charing Cross Road, London, W.C.2.

W. M. H.—We are sorry we cannot identify the extra rapid rectilinear from the lists we have of Messrs. Taylor, Taylor, and Hobson. At a guess we should say the present second-hand value is about £2, but we should think it would be worth while to send particulars to Messrs. Taylor, Taylor, and Hobson and ask them for the original list price. If the lens is still in first-rate condition and covers the plate for which it is listed, you could perhaps get half the original list price for it from a direct purchaser.

F. A.—You should send a formal invoice for the reproduction rights in the two photographs at the end of the month. The usual charge is 10s. 6d. per subject, although 15s. is now being very commonly paid as the minimum reproduction fee. If they don't pay you within a reasonable time we should write them a pleasant letter pointing out that there has been no offer to them of the photographs gratuitously, and that as the copyright is yours, any refusal to pay for the reproductions must be regarded as an act of wilful infringement.

D. D.—The customary operations of making photo-litho transfers are by no means beyond the skill of a photographer. You can get a reasonably good insight into them from the book "Photo-Mechanical Processes," by W. T. Wilkinson, price 4s., from Messrs. Hamptons, Cursitor Street, London, E.C., which deals

- also with photogravure. If you are thinking of working either of the processes it would be to your advantage to have a course of technical instruction, best at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, London, E.C.
- C. H. M.—Either of the shades sent will be quite suitable for the dark blinds, but we should prefer the colder tint. As you are having glass on both sides of the roof, one side will be exposed to the direct sun during the greater part of the day, and we are afraid that you will get a hot-coloured glare through the light brown. With regard to the lens, we think you will do well to get the $f/6$ portrait or anastigmat lens. We have had considerable experience with both types, and there is not much to choose between them, except that the former is a good deal cheaper and some makes have the diffusion arrangement.
- T. C. T.—1. From sixteen to twenty incandescent burners are used under the best conditions to allow of exposures of about four to five seconds with an $f/4$ lens and ultra rapid plate. 2. Usually a single thickness of muslin is the most that can be used. You cannot afford to cut down the light much. Owing to the area of the system of burners it is often quite possible to dispense with the diffusing screen. 3. Within limits decent work can be done, but unless the place is of fair size and well ventilated, a gas lamp makes it insufferably hot. There are two gas installations on the market, the "Powerful" of the Kodak Company, Kingsway, W.C., and the "Howellite" of Messrs. Griffin and Son, Ltd., Kingsway, W.C.
- H. M. B.—Reversed film negatives are by no means uncommon, although we have never seen such a good specimen of a positive "negative" as the one you send. One cause which we think is perhaps the most common is development of the roll-film in a dark-room illumination which can affect the emulsion. It can happen that a negative image is developed on the surface of the film, and if this latter is held close to the dark-room light to look at it a positive may be printed upon the lower part of the emulsion sufficiently vigorous to mask the overlying negative. Apparently there are other causes than this, but these are obscure. Personally we do not think that the specimen you send is caused by the process we have described.
- A. M.—1. You require to apply to the Regional Branch of the Retail Businesses Licensing Order. There are eleven of these in different parts of the country. As you do not tell us where you intend to start the business, the best we can advise you is to be guided by the list recently published. 2. It should not take more than four or five weeks, but, of course, we have heard of cases in which there has been great delay. 3. If you do not trade in your own name you must register. For the necessary forms apply to the Registrar of Business Names, 39, Russell Square, London, W.C.1. 4. Under the Business Names Act you must put your own name on your trade stationery as well as your trade name, but there is no need to have it on showcases or the facia of premises.
- G. C. B.—1. A film filter is quite satisfactory for panchromatic and orthochromatic work. It is usually placed next to the lens diaphragm. So long as you lay it there flat and keep it from getting crinkled by damp it will last a very long time. 2. No, the more bromide you use in a gaslight or bromide developer the more the colour varies from a good black. You want to use only just enough bromide to preserve the purity of the whites, that is prevent veil. 3. If the plates are really thoroughly fixed, no harm will result by washing for only five minutes, drying, and then washing again a week later. 4. We do not know the cause, although the defect is by no means uncommon. Usually prints can be made to bleach uniformly all over by adding a little ammonia to the bleaching bath.
- J. G.—1. You could not depend on re-fixing and washing being of any good for preventing the yellowing and fading. The most common cause is insufficient fixing in the first instance, and if prints have been once washed and dried whilst imperfectly fixed it is no good trying to remedy them by re-fixing. In one case out of perhaps two or three hundred it might work, but in the majority it would not. 2. You can deposit a thin film of magnesia by burning a little magnesium ribbon, but a better plan is to fill the cup with ice-cold water and to photograph it when just a light deposit of dew on the outside has dulled the polish. The

best plan of all is to shield the cup from things which can be reflected in it by making a kind of small, open-ended, tent of muslin, in which the cup is placed. You will find a good many hints on photographing articles of this kind in "Commercial Photography," which our publishers issue, price 1s. 2d., post free.

- J. S.—Perhaps you could learn the carbon process by yourself from the text-book of the Autotype Company, but if you can manage it it would be very much better to go through the course of instruction in the process which the Autotype Company offer free at their works. In either case you had better write to them at 74, New Oxford Street, London, W.C.1. If you want to make small negatives from your half-plate and postcard negative you must rig up the latter against an even light and photograph them down as positives, next printing negatives therefrom; or you can make good prints on semi-glossy paper from the negatives and photograph these together, so that you get a number of the small negatives on one plate. This latter is the more usual plan. There is no book on making these coloured miniatures. Usually they are circle bromide prints, which are celluloid-faced by being dipped in spirit and then hot rolled with thin celluloid. You can get, or could get, the hot roller from Messrs. Fallowfield, 146, Charing Cross Road, London, W.C.2; the celluloid from Messrs. Rheinlander and Son, Rodney Road, New Malden, Surrey, who also supply a cement which dispenses with the hot rolling.

- A. G.—1. Yes, and will retain its activity if kept in the dark. 2. For the best results you should dissolve the sulphite the same day as you use the developer, although certainly amidol can be added to sulphite solution which has been kept four or five days. 3. A blackened tube will make a very good lens hood. You can find out how long it should be only by trial. Make a tube first of stiff paper, and then, by removing the focussing screen, look through the back of the camera from positions corresponding with each corner of the plate. If you can see part of the lens at full aperture being "cut off" by the projecting tube it is a sign that you must reduce the length of the tube until there is no cut-off. 4. We think the confusion as to bromide is not of the principle of its action, but simply as to the manner of use. If a plate has been over-exposed and is put in a developer without an extra dose of bromide it soon darkens over, and the worker, thinking it is fogging hopelessly, takes it out and gets a thin negative simply because development has been for too short a time. If, however, bromide is added the bromide reduces the fogging power of the developer and enables the plate to be kept in the developer for a sufficient time for ample density to be obtained without undue fog.

SUMMARY.

In the course of an article recording some personal impressions of the exhibition of the London Salon, Mr. F. C. Tilney points out the difference in artistic method which he discerns between the sophisticated European workers and those from overseas, whose outlook on Nature is almost always fresher and more direct. (P. 560.)

In his article this week "Practicus" deals with the great variety offered to the present-day photographer in printing papers as regards surface texture and colour of the base and equally colour and tonal quality of the photographic image. (P. 559.)

In a leading article reference is made to some of the views which have been expressed of "likeness" in portraits by recognised critics of paintings. (P. 558.)

We regret to announce the sudden death on Monday last of Mr. G. A. Pickard, head of the Thornton-Pickard Manufacturing Company. (P. 565.)

Summer-time ends at 2 a.m. on Monday next, September 29. (P. 568.)

Some practical hints on the testing of lenses for process and copying work are contributed to "Photo-Mechanical Notes" by Mr. Kenneth Hunter. (P. 565.)

A contributed article deals with the various defects which may arise in the making of sepia prints by toning with hypo-alum or by the bleach-and-sulphide method. (P. 563.)

Working details and illustrative diagrams of a method of selective reduction with bichromate are given by a correspondent. (P. 571.)

Mr. Vivian Jobling describes, with illustrations, how to make a gauge for cutting $4\frac{1}{2}$ by 6 cm. plates from 5 by 4 or postcards. (P. 564.)

A system of daylight development of plates or films carried in envelopes is among the Patents of the Week. (P. 566.)

The Retail Business Licensing Order, permanence of prints, backing plates, half-watt lighting, and lenses for enlarging are among the subjects of brief replies to correspondents. (P. 571.)

In using a large enlarging lantern of the condenser pattern it is an advantage to have a smaller condenser for dealing with small negatives or alternatively to fit the enlarger with a movement by which the negative can be placed at any required distance from the condenser. (P. 557.)

Brushwork on prints is a form of working-up the advantages of which seem to be somewhat neglected. (P. 558.)

The introduction of ordinary lantern slides into cinematograph exhibitions will, it is hoped, provide a stimulus to the revival of artistically coloured slides. (P. 557.)

EX CATHEDRA.

Mixed Lantern Shows.

The interesting entertainment "With Allenby in Palestine" carries out successfully an idea which we have several times referred to—the liberal introduction of ordinary lantern slides into an exhibition which is mainly cinematographic. We trust that this is only the forerunner of many similar shows, and that a revival in the art of making high-class coloured slides will result. Considering the cost of producing a film, that of even the highest-priced slide is small, so that there should be no temptation to show slides which are not perfect in photography and colouring. A point which the promoters of this class of exhibition should not neglect is the securing of something like evenness of quality in both films and slides. If the former are inclined to be flat or soft, it is a mistake to blend with them brilliant, highly-coloured slides. In the show referred to there were one or two dissolving effects, but these were not as good as many which we have seen in the old days. In certain circumstances slides toned by chemical means, as is commonly done with cinematograph films, would probably form a more harmonious combination than hand-coloured pictures.

An Enlarging Point.

Users of enlarging lanterns with large condensers often fail to see the disadvantage under which they labour when using small plates. If we compare two lanterns, with equally strong illuminants, one having a condenser capable of covering a whole-plate and the other covering only of a quarter-plate, the focal lengths of the condensers being in the same proportion to their diameter, we find that in the smaller apparatus only a quarter of the exposure necessary with the larger one need be given to secure the same result. It is, therefore, an excellent plan to have a smaller condenser fitted so as to be interchangeable with the large one when small negatives of considerable density have to be dealt with. Moreover, more range can be obtained for centring the light in the case of extreme enlargement or reduction. Another plan is so to arrange the negative carrier that it can be brought forward into the convergent cone of rays so that a greater portion of this is utilised. This, unfortunately, necessitates a modification of construction which would be difficult with most existing lanterns, but which could easily be made by anyone building his own enlarger. Another desideratum is a fine adjustment for focussing, which can be operated when the lantern is several feet from the easel. In some of the early cantilevers there was a screw adjustment in the middle of the front board, which could easily have been fitted with a long detachable key; an idea has been revived in a different form by Messrs. Houghtons.

Pressing the Button. At first sight nothing would appear to be easier than to actuate the release of a hand camera, yet for all except the most rapid exposures a certain amount of skill is required, and the value of the film and plates wasted every year through unskilful button-pressing represents an income most of us would like to enjoy. The operation is in some respects similar to target shooting, inasmuch as in either case it is fatal to good results to give a jerk at the critical moment. The skilled rifle-shot has a steady pull on his trigger while aiming, so that only a little additional pressure is necessary when he decides to let fly; and it should be the same with the hand-camera user. A thing to be guarded against is holding the camera loosely and "jabbing" at the release with the thumb or finger. Releases vary in pattern, but it is nearly always possible so to hold the camera that the thumb and fingers can be placed in opposition to each other, so that the necessary force is applied in the form of a squeeze. In the folding Kodaks this is usually to be done by placing two fingers under the base-board while the thumb is on the release. As a rule, steadier exposures can be made with a hand trigger than with a ball and tube or Antinous when the camera is held, as one hand has to be entirely devoted to the release, while, of course, the contrary is the case if the camera is mounted on a stand, especially if "bulb" or "time" exposures are to be given.

* * *

Apparatus Repairs. When something goes wrong with photographic apparatus there is often the inclination on the part of the photographer to have the necessary repairs done by some local man, but if the damaged apparatus is of value this is certainly not a wise proceeding. In the first place it is extremely unlikely that any ordinary cabinet-maker has suitable material for the job even if he possesses the requisite knowledge of what has to be done. In addition to this a knowledge is also required of the strain put upon the particular part in order that the job may be satisfactory: this, unless he be also a photographer, an ordinary cabinet-maker cannot be expected to possess. A case in illustration of this came under our own notice recently. A photographer had the misfortune to fracture one of the upper sections of his field-camera tripod, and thinking that it was only a very simple job entrusted the fitting of a new section to a local carpenter. The tripod was made of ash, and as the man had no ash in stock he substituted oak, also making a clumsy job of letting in the brass fittings that grip the turntable. Only a fortnight later when setting up the camera, owing to the fact that the oak had very little "bend," and drew the corresponding ash section much out of its original "bend," the latter snapped, making the tripod practically useless at the time. In the end the job cost about three times as much as it would have done if the services of a competent repairer had been obtained in the first instance.

* * *

"Spotting" or Finishing. We are afraid that many of the modern race of portraitists who have entered the profession without previous experience as assistants in an old-established studio fail to appreciate the value of judicious hand work upon their prints. They are content with the removal of actual defects, and neglect opportunities of improving the general appearance of the picture by a little "working up." When glossy papers were exclusively used it required a considerable amount of skill to work upon them so as to preserve an even surface, but with the almost universal use of matt surfaces anyone who has a little artistic instinct can do much to redeem a print from mediocrity. There is just now rather a tendency to discard brush work in favour of chalk or black-

lead, stumped or rubbed on. While this serves well for toning down flat surfaces it is not suited for filling in details in drapery, and still less for work upon the face, as there is a lack of that crispness which is so characteristic of good brush work. It is not to be expected that a first trial will give entirely satisfactory results, and a good deal of practice upon waste prints may be necessary, but once the requisite knack is obtained the work is very easy. A very necessary factor to success is the possession of really good sable brushes. These should be procured from a good artist's colourman, and each one tested before purchasing; about one in twenty of the "spotting" brushes sold as such are fit for nothing but the roughest work.

SOME CRITICS ON "LIKENESS" IN PORTRAITS.

It is sometimes said that the essential of a photograph is that it shall be a good "likeness," and that whether it is a "picture" or not is only of secondary importance. But do sitters want a good "likeness" and nothing more?

Much depends upon the meaning given to the term "likeness." Ruskin says that "We constantly recognise things by their least important attributes, and by help of very few of those: and if these attributes exist not in the imitation, though there may be thousands of others far higher and more valuable . . . we deny the likeness; while if these be given, though all the great and valuable and important attributes may be wanting, we affirm the likeness. . . . One portrait of a man may possess exact accuracy of feature, and no atom of expression; it may be, to use the ordinary terms of admiration, bestowed on such portraits by those whom they please, 'as like as it can stare.' Everybody, down to his cat, would know this. Another portrait may have neglected or misrepresented the features, but may have given the flash of the eye, and the peculiar radiance of the lip, seen on him only in his hours of highest mental excitement. None but his friends would know this."

This was, of course, written of paintings, but the same points arise in the criticism of photographic portraits. Lewis Carroll clearly recognised that something more than "exact accuracy of feature" is desirable. He deals with the subject in that amusing parody on "Hiawatha" wherein the hero photographed a family group, and—

"Did at last obtain a picture
Where the faces all succeeded—
Each came out a perfect likeness.
Then they joined and all abused it,
Unrestrainedly abused it,
As the worst and ugliest picture
They could possibly have dreamed of;
'Giving one such strange expressions—
Sullen, stupid, pert expressions.
Really any one would take us
(Any one that didn't know us)
For the most unpleasant people.'
Hiawatha seemed to think so,
Seemed to think it not unlikely."

There are few people who ask, as Oliver Cromwell did, to be painted "wart and all." A cynic might say that the most successful portrait is that which flatters enough to satisfy the sitter without going so far as to provoke the derision of the sitter's friends. How often does the receptionist hear, "This one pleases me most, but my friends do not think it is like me."

Hazlitt, who confessed that he found more pleasure in painting than in writing, mentions "likeness" in one of his essays. "There is always something to be done or to

be altered . . . something is wanted to the nose or to the eyebrows, it may perhaps be as well to leave out this mark or that blemish . . . a squint or a pimple on the face handsomely avoided may be a link of attachment ever after. He is no mean friend who conceals from ourselves, or only gently indicates, our obvious defects to the world. I do not conceive there is a stronger call upon the secret gratitude than the having made a favourable

likeness of anyone; nor a surer ground of jealousy and dislike than the having failed in the attempt."

The wise photographer will try to earn this "secret gratitude." He will so pose and light as to emphasise the sitter's most pleasing features and expression, and, even then, there will be something left for the skilful retoucher's knife or pencil—"to leave out this mark or that blemish."

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).

Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).
Apparatus Repairs and Renovations (July 18).
Posing the Head (July 25).
Intensifying Portrait Negatives (Aug. 1).
Workshop Jobs (August 8).
The Personal Factor (Aug. 15).
The Keeping of Negatives (Aug. 22).
Reduction of Negatives and Prints (Aug. 29).
Leaky Roofs (Sept. 5).
Blinds and Curtains (Sept. 12).
Miniatures (Sept. 19).

PRINTING PORTRAIT NEGATIVES.

WHEN we have obtained as good a negative as we can, we have got about half way towards our goal, which is a good print, and, let us hope, also a good picture. Beautiful as were the results obtained by printing upon albumenised paper, this process greatly retarded the progress of photography as an art, for not only did it demand one particular class of negative to give the best result, but there was only one surface. There was little possibility of varying the degree of contrast, although those who sensitised their own paper could effect this to a slight extent by varying the strength of the silver bath, and the range of colour was limited, a warm brown to a purple-brown being all that was obtainable. Any attempt at black or cold tones usually proved unsuccessful, except in a few cases, generally with architectural subjects. This is all changed now, and the difficulty is not to do the best with one medium, but to select from about a hundred varieties of speed, contrast, colour, and texture of surface those which will yield the class of print we require.

The average photographer is, I am afraid, rather too conservative in this direction, and his reputation as an artist is often reduced, unwittingly, in consequence. It is not unusual for one grade of paper to be used, either toned or untoned, for all classes of work. Unless the business is simply that of a "portrait mill" this cannot be considered as satisfactory.

Putting aside for a moment the question of the character of the emulsion used, the surface and colour of the paper have a great effect upon the appearance of the finished picture. Many years ago—I believe before the introduction of bromide paper—a well-known worker said as a gibe: "When you have a negative which is good neither as a photograph nor a picture, print it on rough paper and call it 'A Study.'" This was a rather unworthy knock at those who were trying to break away from the

shackles of albumen and adopting "salted" Whatman paper in the struggle to produce artistic work. Fortunately we have progressed since that date, and rough-surfaced papers have taken their rightful position when broad effects are desired. Artists—I mean those who use the brush instead of the camera—have always realised the value of surface texture as a means of giving effect to their work, and for water-colour have for generations used at least three grades, hot pressed, "not," and rough surfaces, the first being quite smooth, the second slightly rough, and the third with a decidedly granular texture; while a still rougher paper known as "Creswick" was frequently used for bold sketchy effects. Counterparts of all these papers are now to be had coated with bromide emulsion. The smooth and rough grades in various degrees are made by most makers, while a passable imitation of "Creswick" is sold under the name of "Tiger Tongue."

The tint or colour of the paper base is another important factor in the making of a picture, and the general introduction of cream or "toned" papers has made it easy to get pleasing results from negatives which were apt to give harsh results upon a glaring white. These papers give particularly good results in conjunction with sulphide toning, the brown image and cream base forming a very pleasing combination.

The speed of the emulsion often has a very important effect upon the quality of the print, and I always prefer a slow paper to a rapid one, except for enlarging from dense negatives. I do not wish to say that good results cannot be obtained from rapid papers, but that as a rule a longer scale of gradation can be obtained upon slower ones. This is now being realised by some of the manufacturers, and we have very slow papers which require a battery of incandescent lamps or a mercury-vapour tube, to work with a reasonable length of exposure, which will

give prints with perfect gradation from either thin or dense negatives. I earnestly commend these papers to those who are not satisfied with the "quality" of their prints. Moreover, such papers do not call for the extreme accuracy in exposure that is necessary when using the rapid sort. In fairness to oneself as well as to the makers, the latter's instructions as to developers and methods of working should be scrupulously observed. I have known papers which needed a special metol-hydroquinone formula to be condemned because such papers did not give good results with the amidol developer which was successfully used with another brand.

Gaslight papers vary greatly in quality of image, and I have not found them to be so satisfactory for portrait work as bromide. The shadows as a rule are too heavy and the colour too cold, while some do not take kindly to sulphide toning. It must be borne in mind that it is not speed in working nor even a greater degree of contrast that makes the difference between gaslight and bromide. I have used bromide papers which required a yellow light for development, but which needed more exposure than gaslight papers, while the amount of contrast obtainable was about equal with both. I should like to be able to give the names of the various papers I have in my mind, but unless I had tried every brand upon the market it would be unfair to some of the makers to do so.

So far I have dealt with developing papers, because nineteenth-twentieths of the portrait work in this country are done upon them, but there are other processes slower in production with which the other twentieth is made, which for quality of image cannot be surpassed, while they have the added advantage of absolute permanency as far as this can be obtained upon a paper basis. The simplest of these is platinum printing, which is regarded by many as being too expensive for ordinary work. This I consider as a mistaken notion, even at the present high price of the paper, as the price of bromide paper has also risen, and the difference in cost between the two is only about half-a-crown a dozen for cabinet prints. This should not be allowed to stand in the way of those who are obtaining first-class prices, while those whose charges are more moderate can easily obtain twice this amount in addition to bromide prices if the permanency of the prints and their artistic quality are pointed out. Black or sepia tones are equally easily obtained, and there is a choice of surface and tint. Negatives of rather better quality are required than for bromide work, as a rule, but I have seen

some which gave better results with platinum than with bromide when it would not have been expected, the surface of the platinum paper doing away with the impression of empty shadows, which arose when emulsion papers were used.

There are, I am sorry to say, comparatively few portrait photographers who use the carbon process for any large proportion of their work, and this is to be regretted, for it covers a wider range in colour and surface than any other process. The reason for this neglect is, I believe, to be found in the very different class of manipulation required, which does not fit in with other work. Anyone who would use carbon exclusively, except for proofs, would, I believe, find the process as easy and cheap as bromide. The only essentials are a roomy sink and a constant supply of hot water. Exposure is easily provided for by installing one or more mercury-vapour tubes. I found that one of the long tubes fitted with a proper frame would serve for twenty-four half-plate frames at once, the time required being from ten to fifteen minutes. With a little experience it is possible so to arrange the distances of the frames that the whole batch may be taken off at once, no skilled-labour being necessary. If no other process were used all the negatives could be reversed and double transfer avoided. Then carbon printing is easier than P.O.P. if the necessary washings, toning, and fixing is taken into consideration.

I believe many photographers who are not satisfied with their toned bromides would find a great advantage in adopting one or other of the self-toning collodion papers now on the market, as these give very fine results from average negatives. There is, however, a danger of bronzing in the shadows if very strong negatives or those having clear glass in the shadows are used. There is a considerable range of colour and surface of the paper base available, and a good range of tones from sepia to grey by very simple modifications in the treatment. An experiment worth trying is to print a negative in toned bromide and self-toning paper, and to compare the results. In the majority of cases the verdict will be given to the latter.

In this chat I have given no working details, my object being to raise the question in the minds of my readers as to whether they are getting the best possible results from their negatives. There are many who do not care for quality as long as the sitters will accept the prints without demur; but it is not this spirit that has brought photography to the present stage of development.

PRACTICUS.

SOME PERSONAL IMPRESSIONS OF THE LONDON SALON.

THE promoters of this exhibition admit that the great difficulty in its organisation is the question not of what to get in the way of pictures, but of what to throw out. From the far ends of the earth come scores and hundreds of prints with fresh motives, new ideas, unsuspected technical worth, and undisputed artistic feeling. The old brigade of stalwarts at home are very hard put to it to keep their end up. Yet what can be done? It would be palpably foolish to sacrifice new throbbing blood to the claims of the organisms of past decades. The art of photography demands that whatever is worthily done, let it be done where it will, should be recognised in London, shown, appraised, and ranked.

To do this with absolute fairness to the merit of every print submitted would require showrooms at least as big as the National Gallery. Regarding the question from other stand-points, everybody is agreed that the Pall Mall Gallery is plenty large enough. The smaller the show the choicer.

This theory, unhappily, works out to the exclusion of the

representation of many old friends whose work has in no way fallen from its finest standards. The practice of the theory has likewise its regrettable side, for it means that the world's output must rely for its recognition upon the judgment of a handful of Englishmen.

These points are as old as photographic exhibitions. They will never be settled to the blissful satisfaction of all concerned. The only way to keep pace with the lifting level of artistic expression in photography is to have more frequent exhibitions. Failing this, the selection must be still more rigorous than it is. Perhaps it would be fair to show no more than one example of any man's work.

To stroll round the Pall Mall Gallery is to be persuaded that the principles applying to artistic photography are now thoroughly understood by great multitudes of workers. The best things are perhaps not very much better than the best of past years, but there are many more that come nearer to their standard. It is impossible to find here a print that has not

much to recommend it; and it appears that the gallery could have been filled over and over again with work equal to the lowest level of things shown.

All this means unquestionably that pictorial photography has established itself as a satisfying means by which those who have emotions to express can do so in an artistic way.

It is no less certain that the practice is highly educative; for one sees the results of original and individual observation on all sides. The fascinating mysteries of light are obviously drawing countless votaries in all the Dominions. Appreciation of natural effects has entirely taken the place of mere cheap-jack "stunts" which used to flood the Salon years ago. The stunts, I hope, have found that the great B.P. (and incidentally the B.J.) cannot be fooled. Since Nature and Art have knocked up a closer acquaintanceship in pictorial photography they have rendered it a more popular, more earnest, more satisfying and more educative cult. And of another thing we may be certain: the dealers must find this change to a "sweet reasonableness" more profitable.

Perhaps one of the most striking examples of the appreciation of what may be called the inner call of Nature is F. O. Libby's "The Land of Desire" (21). This, at a close view, one would dismiss as an empty blue-tinted print, positively unphotographic in method, and exhibiting in subject none of the characteristics which the camera is chiefly fitted to portray. But let the spectator get far enough back from this print to see it as it should be seen, and he will find it take on a new significance. He will then appreciate what the photographer sensed in contemplating the actual scene: the vastness, the loneliness, the uncompromising lack of the pretty littleness of landscape, the inexorableness of Nature.

When a photographer has arrived at this point in his observation and susceptibility before Nature, he has become something of the poet, at all events, and it should not be a far step to become an artist of the true sort. That completion depends upon technical skill to secure pictorial wants, and in photography such skill is fortunately not hard to come at.

It appears to me, though I hate to say it, that this unsophisticated, unseptic outlook on Nature prevails more in the fresher conditions of the Dominions than it does in the Old Country, where sophistication, bred on a medley of traditions, keeps our men always fitful; trying a "new line" here and "another style" there. Much cleverness is expended in these attempts at picture-making, and the results are usually charming enough; but it is the charm of the echo of past thought and past ideals. No doubt the Colonials, too, would gladly arrive at this if they could; but they can't. Their environment pulls them out of the temple into the open. Tradition, to them, is a thing to take in doses, for a change. It is in our blood. That is why we have our Misonnes, and Keighleys, and those others who build up genre work with colossal patience, all for the sake of an idea.

In L. Misonne, whom I am truly glad to welcome back, there is an obvious reaching after the traditions of later (not the latest) French landscape painting. It is an ideal of much sweetness; but, of course, it is not in the spirit of the uninitiated youth with a camera. Misonne's "Le Passage d'Eau" (198) is as near a reproduction of a Corot as a photograph could well make. But because, in "Dinant" (205), he weds the irresistible charm of his style with a touch of the direct breath of Nature, one is the more stirred with this bewitching town and river scene.

P. Douglas Anderson hails from San Francisco. In his print called "A Corner, Palace of Fine Art" (228) there is the clearest appreciation of the quality of luminosity that has ever been presented to my eyes by photography. On the columns and walls of the building the sunbeams tell with force that is relatively true to Nature; but something yet is saved for the sky itself, which is more than merely high in tone. It is luminous.

It has a distinctly different quality from that of the parts that only reflect light, and that difference is conveyed to the mind as the difference in quality between direct and reflected light.

A few other prints come near to this example in the same respect; but, generally speaking, photographers have not yet initiated themselves into the esoteric mystery of luminosity. Can't they see it; or don't they care? Perhaps they are still so dead-set upon that sort of "quality" which comes of low rich tones that they will not be drawn aside from their art to our nature!

There are two other prints that are veritable Nature songs: two landscapes by John Paul Edwards, of California, "Hills of California" (116) and "The Valley of Peace" (117). The first not only presents a scene made up of the romance that lies in a scenic composition of hills and trees, but shows how the beauties of form and composition are enhanced a hundred-fold by the light-entangled vapour that fills all the spaces before the different planes of tree-banks and hillsides. "The Valley of Peace" is an open expanse beyond which hills seem to occur for ever as one looks through the light veil that shrouds them. This naturalism has a universal appeal. Everyone with whom I compared notes extolled these two things. Nevertheless, their attractions are not usually characteristic of the best camera-work in this country.

However, Lionel Wood, an Englishman, has triumphed on similar lines in his astoundingly convincing "Aeroplane in Flight" (165); where the machine detaches itself in a wonderful way. It is in the air. You can feel space all round it. Below, the earth is dimly seen, with its fields and hedges, across which a mere white scratch of a road stretches from side to side. Up in front and yet somewhat below the machine is the tip of an enormous cloud shining in the light. Perhaps it is because aero-photography has started from a new point of departure that it has been able, in this instance, to present its own case, free from the sophistications of the camera-studio.

"The Sunlit Sands" (147) is from New South Wales. Its author, M. Mackinnon, has successfully given the horizontal feeling of the stretch of level ground that carries the eye back without any need for the reasoning and adjustment necessary in fully half the pictures of similar subject-matter. J. C. Carlton (Los Angeles) gets the same flatness of retiring ground in his shore scene, "The Closing Day" (224), overspread by a superb sky.

John Keane is a man on our side again. His "Waterloo Bridge" (340) has air, breadth, and light. It gives the grandeur of the Thames; but there is nevertheless a touch of something lacking to give that compelling confirmation that rouses even the jaded mind to enthusiasm. That touch reappears in "To the Open" (402), a yacht speeding through a glistening sea. But here again one learns that its author, Arthur Ford, is an Australian.

If these generalisations are anywhere near the truth, it would follow that the literary note, poetry and romance derived from tradition rather than from Nature direct, would be stronger in Britain. And this conclusion is, indeed, borne out by facts. Alex. Keighley catches this spirit here as ever. "The Rising Moon" (83) is inspired by an inner consciousness of what such subjects should be, as well as by the actual view. Nobody who knows believes that this print is the result of an exposure upon such a scene as is here depicted. And on examination we find that the texture of the trees is sophisticated. It is not unlike wire netting. The trees of the wood have none of that impenetrable solidity which, even in winter, they present under a night sky with the moon behind them. But the ruling mood is there right enough. Again we have all the romance and mood of an Alpine valley in "A Swiss Landscape" (82); but Mr. Keighley has not thought it necessary to give us a luminous sky. His best success is, in reality, the effort in less traditional picture-making called "Early Morning" (87). This "goes back"

in proper stages to the uttermost distance; it gleams with light which catches the wind-ragged smoke from the chimneys of an old town through which the ample surface of a river reflects the light from the sky. It is less "romantic" in the literary sense of the word, but far more naturalistic.

S. Bridgen starts from the same point of artistic vision as F. O. Libby, whose "Land of Desire" I have referred to. Mr. Bridgen feels the majesty and tranquility of late evening in his dark scene of large trees and wide sky. "A vast and tender peace, etc." (168). This also must be seen from a proper standpoint, when its full poetic purport finds expression. There is a different mood in W. Burgess's "Romantique" (414). It is a Watteau setting without the picnic and the music-party. Evening has come and gaiety has given place to brooding, but the charm of Watteau's artificiality remains. The visitor will find many examples from over the seas, in which the romantic note and the note of sentiment are wrongly struck.

When the Colonial mind attempts the romantic with the help of the figure, it usually "o'erleaps itself and falls upon the other side." It is a kind of thing that does not come naturally to a mind that has not been steeped in the romance of classical art; but by the effort of a severe pose the sons of the Dominions have often made outstanding successes in pictorial romance. To the Britisher it is as easy as shelling peas. He can do it without the adventitious aid of darkness and mystery, such as Fred Archer relies upon in "The Suppliant" (253), where a tiny figure in the nude bows itself before a black idol in a vast and dismal hall. Louis A. Goetz gains nothing by his little figure contorting itself in a manner quite beyond the occasion of a "Greeting to the Mountain" (260). Nor are the maniacal acrobatics of "A Goddess of Nature" (42) anything but a blot upon a superb mountain and shore view, sent by Louis Fleckenstein; and the same criticism is justified in his "Play of the Winds" (108), where similar conditions and qualities exist. Fortunately, Mr. Fleckenstein's portrait and landscape reputation is proof against these little figure shortcomings.

The introduction of the nude into a landscape setting has become a distinct style of work, and has been carried to a high level here at home. I think I am right in saying that Miss Kate Smith started the ball rolling. To this show she sends "The Little Nymph and the Little Chickens" (431), in which the nymph wears draperies.

Perhaps Francis Jay has scored highest this year in the classical style of work by his rather dark, but well-realised fancy, "La Source" (75), where a nude damsel crouches, not quite at the source of a stream. Here there is a distinct idea: a personification of a natural phenomenon in the classic manner. A. F. Kales's "Spirit of the Winds" (104), though a fine print, has less inspiration. His figure is tortuously posing and waving a sheet, or a blanket. There is nothing of that silent inner spirit that has significance in classic allusion. His "Nude Study" (105) frankly disclaims such allusion, although it is placed in a dim place, and is obviously struggling with some mental or physical difficulty. As a nude study it is certainly beautiful. Its flesh, most of which is in a half-light of even quality, receives the touch of a gleam on the face, neck, and flank; and as a specimen of womanly loveliness it is surely all one could desire. I speak for myself.

The nude studies of Mr. and Mrs. Bertram Park, are however, all things considered, the best in the show. Yvonne Park's exquisitely rendered tones and textures in "The Casket" (145) are an æsthetic joy. Here is perfect consistency in the tonal scheme; gentle, but most telling relief, fascinating lighting, subtle modelling; unstrained, yet unhackneyed posing, and delightful quality, especially in the head and neck. The way the contours are managed evinces great feeling and skill. Bertram Park's "Study" (2) is perhaps more entirely Greek in its lines, and is a stronger presentment altogether, but it

lacks the irresistible fascination of "The Casket." Its middle tones are prevalent, as in Mr. Kales's "Nude Study"; but it has, as well as high-lights, slight passages of deeper shade which give it the look of stone, and possibly have much to do with the flying back of one's thoughts to the sculpture galleries of the British Museum as one contemplates the print. I should also mention "Study" (157), an upright figure, beautifully lit and modelled. "Pandora" (22) is another nude by Mrs. Park, but little less fine than "The Casket."

One of the works which will impress the visitor most will be F. J. Mortimer's further version of his last year's success with troops at a railway station. This is "The End of the Trail" (85). Perhaps the grouping of the men is in this print even more successful, although the composition misses the fine arch that was of such striking importance in "The Gate of Good-bye." But here the figures have more individual interest. The lighting is exceptionally fine, and the relief of light and shade effective to a high degree. A similar subject, but one which is less deliberately pictorial, is Hector Murchison's landscape called "The Fortune of War" (43), which depicts a large squad of German prisoners laden with timber marching down from the hills. It is a striking work, full of bustle and light, and is just the kind of valuable document we did not get from the post-impressionistic and futuristic draughtsmen whom a sapient Government commissioned to make exactly such records.

Humour is not abundant; but John H. Anderson's "Gentle Saurians" (4) are distinctly comic, with their brotherly affection and smiling expression. They make a capital composition, and have that ever-present quality which distinguishes all Mr. Anderson's work. There are several examples of it here. To European eyes there is comicality likewise in the excellent pair of Japanese actors contributed by C. P. Crowther, which are entitled "No" "Performers" (268 and 283). They are striking subjects rendered by beautiful prints.

A large and powerful example of the gum process apparently is sent by J. MacSymon, "A Roaring Torrent" (112). It is a most effective piece of work, masculine and broad. Another print, remarkable for the process by which it is executed, comes from W. R. Bland, called "Under the Scour" (368). This choice piece of woodland scenery has a texture very like that of the gum process, well suited to the bark of the foreground tree. The variety of effect offered by different printing methods is a matter of importance to resourceful and discriminative workers. The last-mentioned pair of prints show a style of treatment well suited to their subjects. The delicate nuances of an effect of mist, however, are not served by a granular process; and Walter Selfe's beautiful "Autumn Morning" (131) gains all it needs in the smooth method he adopts. It shows the remarkable effect of transparent haze through which the details of malt-houses or oast-houses in the middle-distance can be discerned if one looks for them. A similar clean and smooth method renders the whole tale of architectural details in J. R. H. Weaver's Oxford interiors, "Entrance to a College Chapel" (72) and "The Divinity School" (80). In the same category would come Ch. H. L. Emanuel's choice view of "The Courtyard" (243).

Portraits and figure studies are, perhaps, less remarkable on the whole than landscapes. Certainly the British photographers are holding their own in this section. The most outstanding examples are from Herbert Lambert, who sends several things of real beauty. He works in a perfectly unaffected manner, but in various styles. There are large vignettted heads in grey, and half-length figures which are broad and full in tone, but what fascinates one most in them all is their human charm. Such things as "Madeleine" (111) and "Portrait" (204) are covetable, even though the sitters be quite unknown. W. Croke is seen to best advantage in "Sir Henry Wood" (188). Louis Fleckenstein repeats his former triumph of the "War Widow" in "Miss Lucille S." (315), a gloriously-toned

and animated portrait, of fine pose and splendid lighting. Less choice in treatment, but of great power and charm, is the "Happy-go-lucky Mexican Boy" (195), in which the lighting and management of the edges show much artistic feeling. Marcus Adams heads the ranks of quite a number of photographers contributing baby portraits of all descriptions.

R. Polak continues his most ingenious reconstructions of Dutch seventeenth century genre. He is beginning to feel the need for gradation and massing of tone, and the avoidance of hard edges, and his grouping is less scattered. These clever works are, of course, no longer novelties, but they maintain their charm, and I believe that their author will do even better yet with them.

One of the angle walls is filled with prints of a decorative character in the Japanese manner. They show fine taste and feeling.

Works in colour, too, may please some visitors. I confess to being left cold by these never-ending attempts to push photo-

graphy where it evidently refuses to go, although it must be confessed that the examples by Fred Judge come very near to the colour of nature. His process is the most hopeful of them all. But with pigments that are not sufficiently transparent it is impossible to avoid a sad degradation of colour in the darker parts, where three heavily charged transfers of pigment have to be superimposed.

There are many choice works on the three screens, but they will get less attention than they deserve, both from visitor and critic. It is impossible to see them without uncomfortable eye-strain and undignified posturing, owing to insufficient illumination, reflection in the glasses, and low position. If these screens were placed transversely, instead of longitudinally to the greatest measurement of the room, some of these disadvantages would be avoided.

It will be agreed that the show altogether, and considered from every standpoint, is the best we have yet seen.

F. C. TILNEY.

THE PRODUCTION OF PERFECT SEPIAS.

I THINK that the majority of photographers will agree, when I say that more poor sepia prints are turned out than black and whites. Also that the production of sepias is often associated with much trouble, waste, and ultimate disappointment. The reason is simple, for in all popular sepia processes a black and white print is required first of all. Therefore, sepia means extra work, and secondly there is no law that a passable black and white must necessarily result in a passable sepia if toned. Therefore, sepia means more risk.

The extra work cannot be avoided, but the risk can be minimized to the point of guaranteeing twelve perfect sepias from a dozen perfect black and whites. It is only necessary to study the peculiarities of the process, and to take sufficient care in carrying it out.

The most common faults of bad sepia prints are:—Muddiness and poor quality of colour; double tones; spots; blisters, washiness, and "weight." This latter being that heaviness gained sometimes in drying.

Let us take them singly, and consider their most common causes and the simplest means of prevention.

Muddiness.

Sepias that are muddy or those whose colour is not pleasant may be produced in different ways. A thin or flat negative will not readily give a print which will tone well. An over-exposed print may appear fairly good in the black and white stage, but tone muddy in spite of careful toning. Stale developer or an excess of bromide will also influence the quality of prints which are subsequently toned. A weak sulphide solution, or an out-of-condition hypo-alum bath will cause sepias to be poor in colour quality.

To obtain a pleasing colour, good negatives with plenty of body in them should be made in the first place. Fresh developer should be used for the prints and the bromide used carefully. Exposures may be on the short side but never over, unless printing on a vigorous paper from a bold negative, in which case over-exposure and quick development may prove decidedly useful. If the toning is done by bleaching and sulphiding, the sulphide must be fresh and not too weak. I find a 1 per cent. solution right for most papers, but opinions differ on the point, some using stronger and some weaker baths than this. With weak solutions there is a risk of over-working the sulphide, however, and, if a quantity of prints are being put through, it is wise to keep renewing the bath. Also to soak each print separately for at least a minute before potting another on top of it.

With hypo-alum, to get the best colour the bath should be just ripe, not too fresh and not too old. A fresh bath has a tendency to give pale yellowish tones, and an old one dark, cold tones.

Before bleaching a print, if it is on the weak side, a preliminary

soak in the sulphide solution will have the effect of making it deeper and colder.

A flat print can be improved by adding to the bleacher an amount of potass bichromate equal in weight to the ferricyanide.

Improved colours can similarly be obtained by soaking the prints in bichromate solution—of a fairly deep salmon tint—previous to bleaching in the usual bath.

Very cold tones may be produced by giving the bleached prints a run through amidol developer before sulphiding. The tone will depend on the time they are in the amidol; the longer it is the colder the tone.

Double Tones.

Who has not at some time or other seen a toned enlargement marred by ugly blue-black patches? I mention enlargements rather than small prints, because the former are more liable to the particular markings, and also more likely to escape immediate destruction when stained or double-toned. Admittedly, a good worker should not pass an enlargement where he would destroy a small print, but nevertheless there seems to be a much bigger proportion of double tones among large stuff than small.

By far the commonest cause of double tones is imperfect fixation. This is why the large stuff is more likely to suffer. A dab and a push may suffice for a postcard, but is useless for a 20 by 16. A print intended for toning—or, in fact, any bromide or gaslight print—when developed should be immersed thoroughly in active fixing solution; in other words, it should be attacked all over by good, clean hypo at once. If any delay is necessary between development and fixing the print must be kept immersed in pure water or in a recognised stop bath. A bromide or gaslight that is being "fixed," in places by hypo solution and in other places by air bells or remnants of developer, will record the position of such air bells and developer on being toned.

The record will be in blue-black spots and patches, so the way to prevent such double-tones is obvious.

Similar markings have been said to occur owing to excess of heat when using hypo-alum, also to air bells in the toner. In both cases prevention is easy.

"Faking" in development and local reduction of a print in the black and white stage will cause double toning, but in these cases the secondary tone will be paler or yellower than the normal.

Gaslight prints from very thin negatives are liable to tone in alternate warm and cold streaks. Contaminated developer will cause similar markings to appear on toning.

There is one kind of double-toning which is not so obvious or so offensive. It is a peculiarity of certain papers, and consists of cold high-lights and warm shadows.

Some prefer this effect to the normal, but if not liked it is easily avoided by changing the grade—not the brand necessarily—

of paper. In one well-known make are two kinds of platino-matt bromide: one tones to deep brown and pure white, the other to deep brown and pale blue. In black and white they are almost indistinguishable. Another equally popular brand gives pure black and pure white, which, on toning, becomes brown-chocolate and cream. This sort of double-toning is worth cultivating.

Spots.

All things photographic suffer at times from spots. Sepias are no exception. White, red, puce, blue, and black are the varieties I have met and combated. Maybe there are as many other kinds as well.

White spots are caused by hypo dust knocking about the work-rooms. A speck of this, too small to be seen, may lodge on the print and form Farmer's reducer when the print is bleached. Hence the white spot. Another white spot is due to over-fresh paper. This spot appears on development, and is not unlike that produced by an air-bell.

Red spots may be brought about by impurities in the water supply. A linen bag tied over the tap will keep grains of dirt and metallic matter back and helps to prevent spots. Dark spots—seen by transmitted light—in the paper itself (not the emulsion) often give rise to red spots on the surface when toning. Such paper should be rejected, or the spots kept to dark parts of black and white pictures where they will not be noticeable.

Puce or purple spots that appear during drying are due to dust. At the first sign of them the drying-room, or cupboard, or rack should be thoroughly cleaned and overhauled.

Blue spots may be caused by traces of alum in the print, when it is bleached. Any other matter capable of forming Prussian blue with ferricyanide will give rise to these spots if such matter is in the print, or the water, or adhering to the dishes. Care and cleanliness are the best preventives of blue spots. They can be removed sometimes by application of a strong alkali, or by hydrochloric acid, but their removal is not a sure proceeding at any time.

When using the copper-ferricyanide method I have often met with black spots, but have never been able to trace the cause or devise a cure. Re-development will, by turning the rest of the colour black, cause them to disappear, leaving the print as it was prior to toning.

Blisters.

Blisters usually occur with delicate and poor papers, and are caused by air getting under the film of gelatine. Just how the air gets there it is not always easy to see, though some papers are so porous that a bubble imprisoned beneath a "face-up" print will percolate through the paper until it is enclosed between the paper and the gelatine.

Warm or strong sulphide solution will tend to cause blisters, as will also a falling stream of water or an over-long washing. Prints from the hypo-alum bath may be blistered by a sudden chill. To prevent these unsightly marks—which may dry down but don't often disappear totally—care should be taken with the dilution and temperature of sulphide and an anti-splash device used on the washing tap. Washing should not be protracted—ten minutes should suffice. With hypo-alum, prints should be allowed to cool down before being put into cold water. A hardening fixing bath is useful when delicate papers are being handled.

Washiness or Want of Depth.

The washed-out yellowish sepia print is not a thing of beauty or one to be repeated.

It is usually brought about by insufficient care in making the black and white print, but may be due to other causes. A good print which has been correctly exposed and developed will not tone washy unless something is wrong.

Hypo in the print or bleacher will do the mischief. To guard against this, prints may have a preliminary soak in pink permanganate solution. If the pink colour is not turned yellow or entirely bleached in two minutes the prints are safe for bleaching. If the bleacher is not known to be uncontaminated, new should be made up.

Fresh hypo-alum has a reducing effect. This can be corrected by ripening the bath with a few waste prints or pieces of bromide paper.

Heaviness Gained in Drying.

To guarantee that a print will not gain depth when toned and dried requires the consideration of at least three factors. First, the make of paper. Some makes—and also some varieties of the same make—dry up differently to others. Second, the development of the print; and, third, the method of toning. The make and variety of paper must be studied to find out its tendency in this direction. If it tends to dry up dark, then the development must not be overdone. Sufficient exposure should be given to ensure barely full development in one and a-half minutes at 65 deg. F., using a normal developer. With extra bromide new calculations are necessary which may need experiment to verify.

Prints from flat negatives should be slightly under-exposed, so that when fully developed they will look a good shade too light. When toned and dried, the print should be correct in depth and of a fairly good colour. Slightly intensified results can be obtained by using the dichromate bleach on the fully developed but light print, as mentioned in the paragraph on "muddiness."

THERMIT.

A DEVICE TO FACILITATE THE CUTTING OF PLATES FOR SMALL CAMERAS.

MANY users of the vest-pocket type of camera, taking a plate $4\frac{1}{2} \times 6$ cm., probably, like the writer, use also plates of 5×4 or postcard size, and may welcome a ready means of cutting up the larger plates for use in the smaller camera. This practice has the advantage of making it unnecessary to stock an extra size of plate and also of ensuring that the small plates are accurately cut. Many of those obtained in the ordinary way are so much below nominal size as to leave practically no hold in the metal form of dark slides. At the same time, the ordinary thin glass used for 5×4 plates will never jam in a slide, as sometimes happens with the extra thin glass of which the small plates are made.

The apparatus consists of a cutting gauge of grid form, shown in fig. 1, and a base board with recess for plate shown in fig. 2.

The base is provided with two strips of wood to act as stops for the gauge, which is used in the following manner:—

The edge of the gauge marked L is placed against the stop L on the base, and three cuts are made on the plate lengthwise, using the edges "Y" on the gauge as guides for the diamond or glass-cutter.

The gauge is then reversed so that edge S is brought against

stop S on the base, and three cuts are made across the plate, using the guide edges "X" in this case. The plate will then have the appearance shown in fig. 3.

The outer edges are broken off by insertion in the groove provided at the edge of the base for this purpose, and the plate is then broken at the cross cuts. It will, of course, be understood that the plate is cut on the glass side, and that to break off after cutting it must be bent away from the cut to part the glass, and then back again to sever the emulsion. If, however, the cut plates are to be packed away before use, it is better not to sever the emulsion in each pair, as they can then be folded face to face on the gelatine hinge thus formed, effectually preventing rubbing of the sensitive surface.

During the handling and cutting of plates it is advisable to protect the film side by means of a piece of clean white paper the size of the plate. This enables the plate to be gripped between the fingers when breaking off and keeps the surface quite free from glass particles.

If the plates being cut up are post-card size it will, of course, involve only one cut lengthwise, but in this case it is important

to see that the edge L on the gauge or stop is adjusted to bring the cut exactly central with the particular glass-cutter in use, whereas with a 5 x 4 plate a slight variation only affects the width of the strips which are cut off and thrown away.

The construction of this piece of apparatus is fully shown by the sketches which are dimensioned in inches, allowing for the plates

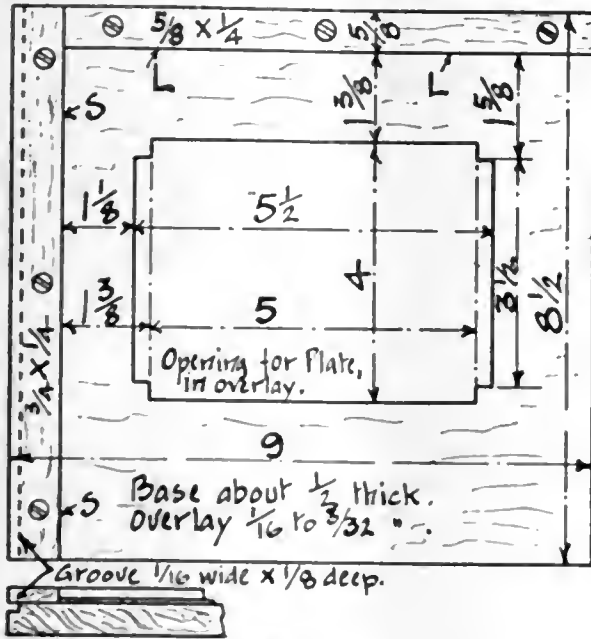

Fig. 1.

being cut $\frac{1}{2}$ mm. smaller than the nominal sizes. It may be mentioned, however, for the benefit of less experienced workers in wood, that the gauge (which is the only part requiring accuracy) can be cut out with a fret-saw and the edges trued up with a

Fig. 2.

sheet of glass paper wrapped over an old negative glass of about 5 x 4 size, thus forming what is virtually a very wide file.

To those who do not possess a glazier's diamond, the following hints upon the use of wheel glass-cutters may be of service:— (1) Give a fairly quick and light stroke such as would be used in ruling a line on paper with a pen and ink, and holding the cutter as the pen would be held. Heavy pressure is not necessary

and only results in a jagged cut. (2) Incline the handle of the cutter slightly away from the ruler edge; this will keep the wheel always against one side of its bearing and ensure a straight cut.

The writer has cut up some dozens of 5 x 4 plates by this method, and has found it very successful; a noteworthy advantage being

Fig. 3.—Cut Plate.

that if in the case of plates suspected of staleness, the cutting off of the outer edges removes any risk of marginal fog in the smaller plates, where the encroachment on the area of the picture becomes a matter of consequence.

VIVIAN JOBLING.

DEATH OF MR. G. A. PICKARD.

We much regret to announce the death, very suddenly, on Monday last, September 22, of Mr. G. A. Pickard, head of the firm of the Thornton-Pickard Manufacturing Co., Ltd., Altrincham, at the age of sixty-eight.

Mr. Pickard had been chairman and director of the Altrincham firm of photographic apparatus manufacturers for many years, succeeding in that capacity his brother, Edgar Pickard, whose death in the early days of the firm's history deprived him of an active and skilled collaborator. His own delicate health for many years past prevented him from taking an active part in the trade conferences and other functions connected with the industry, and indeed for the past few years the claims of his own business were as much as his measure of physical vitality could discharge. Nevertheless he retained an active interest in it until the time of his death. Those who had occasion to visit him in Altrincham or to meet him on the rare occasions when he appeared at a trade gathering will remember with pleasure the invariable old-time courtesy which was characteristic of his manner and was part of his nature.

The funeral is announced as having taken place yesterday (Thursday) at the Friends' Burial Ground, Ashton-on-Mersey, Sale.

Photo-Mechanical Notes.

Testing Lenses for Process and Copying Work.

The variety of lenses in regular use for copying and process work at the present time is so large that one is inclined to believe that almost any lens of suitable focal length can be satisfactorily employed in practice, provided due regard is paid to its limitations. But for successful work it is desirable that these limitations be first discovered, and it is more satisfactory to examine a lens in a methodical way, so that one may know exactly how far one may go, than to risk a job turning up one day which the lens is unable to cope with. A 15 x 12 R.R. lens of ancient though reputable manufacture may be found to be quite efficient for the average run of half-tone work up to say 10 x 8, but may fail absolutely on a 15 x 12 line job; while its employment on three-colour work would most probably be fatal to good results. Yet there are 15 x 12 R.R. lenses being used daily for three-colour half-tone, and producing excellent results.

It is not a difficult matter to test a lens thoroughly on a camera, and a few suggestions for those who have the time and inclination to undertake the work are contained in these notes.

A camera one or two sizes larger than the plate the lens is sup-

posed to cover should be used, in order that the definition given by the lens at the edges of its circle of illumination may be clearly seen, and if the camera is mounted on a photo-engraver's stand of suitable length, and a considerable range of reductions is obtainable, it will be an advantage. An ordinary studio stand can be used, however, provided care is taken that the back of the camera is absolutely square with the easel carrying the test object.

As a test object one of the special charts obtainable from most lens manufacturers is best, because the collection of weird designs usually found along the edges and in the corners of these charts readily indicate, by becoming more fantastic than ever, any irregularity in the correction of the lens. The chart is pinned up on the easel or wall and illuminated as evenly as possible by daylight or arc lamps. The parallelism and rigidity of the camera should also be carefully checked, and care should be taken to see that the plate in the dark slide occupies precisely the same position as the focussing screen, as otherwise faults of the camera may be unjustly attributed to the lens. The lens should be exactly in the centre of the focussing screen or plate.

A rough inspection of the image of the chart on the focussing screen may then be made, and the centre of the chart focussed as sharply as possible with the camera arranged for about $\frac{1}{4}$ diameter reduction, or the greatest reduction which will allow the whole of the screen to be covered by the image. For instance, if the chart employed is 3ft. \times 2ft. and the camera a 15 \times 12, the image would fill the screen at just under $\frac{1}{2}$ diameter reduction, and the preliminary examination should be made at this reduction. In the case of lenses of long focal length, two or four of the standard charts may be used; in fact, the larger the chart the better. The greater the reduction, the more searching the test becomes, as the lens is being used over a wider angle, and it is mostly when copying large originals at a considerable reduction that lens troubles occur in reproduction work.

Having examined the image visually on the screen at various stops, a plate should be exposed at full aperture. We will assume that a 12 \times 10 lens is being tested. The first exposure should be made on a 15 \times 12 plate, so that the falling off of illumination and definition at the edges may be recorded. Then stop down to f/16 and make another exposure. These two negatives will suffice to show the practical covering power of the lens, and it will probably be found, in the case of a modern lens, that the f/16 one shows the 15 \times 12 plate well covered, although the lens is nominally only supposed to cover 12 \times 10.

Now we turn to examine the behaviour of the lens in detail on a plate of its own size. Alter the position of the camera so as to get the image of the chart to occupy exactly the 12 \times 10 plate. Then focus at full aperture, and get the image as sharp as possible in the centre of the screen. Three test plates are sufficient, one taken at full aperture, (usually f/8 or f/11), one at f/22, and one at f/45. These will enable the experimenter to judge the largest stop that can be safely used for various classes and sizes of work. The "full-aperture" plate will show any defects of the lens by deformation of the designs on the chart. Lack of correction for blue-violet rays will be indicated by a general lack of definition all over on the negative, although the visual image was sharp. Pronounced spherical aberration will produce a similar effect, but in this case the visual image will also be unsharp. Astigmatism will be indicated by the appearance of the vertical and horizontal lines on the chart, particularly those at the edge; if both are equally sharp, there is none present. Distortion can be readily observed by placing a steel rule along the negative, against one of the lines which is straight on the chart, whereby one is able to see if the line has become curved or distorted by the lens. The other two negatives will serve to show how much any apparent errors are reduced or eliminated by the use of a smaller stop. A comparison of the three negatives will also show whether the focal plane of the lens shifts with different stops, a peculiarity occasionally possessed by even high grade anastigmats, and one which causes considerable annoyance in practice.

If the lens is to be used for three-colour work, a rough test as to its suitability and colour correction is obtained by making three negatives of the chart through tri-colour gelatine filters on panchromatic process plates, with a fairly large stop. In this test

the focussing should be done through one of the filters, and the filters used must be perfectly clean and free from finger-marks, etc. Cemented filters should not be used unless they are known to be of the very finest quality and to have no appreciable optical defects of their own. When these three negatives are obtained, any difference of focal length under the different filters will be noticeable, and variation of the size of image, commonly called the "register," is discernible by superimposing the negatives, or by carefully measuring the length of one or more of the chart lines.

The tests above outlined do not, of course, give results to a very high degree of accuracy, neither do they indicate all that the optician wants to know about a lens, but they are sufficient to enable the user to define the practical limitations of his lenses, and when he has done that, he will know what jobs he can tackle successfully with each lens at his disposal. Further, the test negatives will prove extremely useful if at any time he should have occasion to complain to the manufacturers regarding the performance of any particular lens.

E. KENNETH HUNTER.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for patents, September 8 to 13:—

- CAMERAS.—No. 22,294. Photographic cameras. B. Hinkler.
FLASH LAMP.—No. 22,493. Magnesium lamps for photography and fuel cartridge therefor. A. de Montazel.
PRINTING FRAMES.—No. 22,181. Photographic printing frames. J. L. Troubridge.
SCREENS.—No. 22,119. Cinematograph, etc., screens. H. Dewey.
CINEMATOGRAPHY.—No. 22,410. Moving picture projecting machines. W. E. Johnson, S. Stratford.
CINEMATOGRAPHY.—No. 22,230. Production of films for cinematographs. L. Sawyer.
CINEMATOGRAPHY.—No. 22,043. Cinematograph films and manufacture thereof. J. E. Thornton.
CINEMATOGRAPHY.—No. 22,044. Machines for printing cinematograph films, etc., photo-mechanically. J. E. Thornton.
COLOUR CINEMATOGRAPHY.—No. 22,045. Cinematograph colour films.—J. E. Thornton.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DEVELOPING TANKS.—No. 119,246 (Sept. 3, 1917).—The invention relates to developing tanks for photographic films or plates carried in envelopes, of the type in which one or more resilient strips or guides forming light-tight slots are provided in the lid through which the envelopes can be withdrawn for exposing the films to the developer.

There is provided above the guides a sliding lid having incisions which engage with the shutters of the envelopes and cause them to be bent so that light-tightness between the guides is further secured, or alternatively the guides may be curved longitudinally so as to interfit loosely.

In the drawings 1 is a tank which preferably may be wedge-shaped by either or both of the sides slanting at the base, and with a hole in the side close to the bottom, from which a small tube 2 is connected with a funnel 3 fastened to the side of the vessel. The bottom may slope downwards towards the hole in order to drain the tank thoroughly.

The top of the tank has a cover 4, which consists of a frame with guides in the form of cylindrical india-rubber cushions 5, firmly mounted in bearings in the frame. The cushions preferably are of very soft rubber on hard cores 6, for example, of wood, and which are so mounted as to be fixed or movable in the frame of the cover.

By reason that the core 6 is rectangular, while the rubber cushion is of circular cross-section, two air-cushions 11 (Fig. 7) are formed, and this tends to secure a softly yielding and opaque connection.

Above the cover is an open frame lid 7, the sides of the open part of which are provided with incisions 8, so that there are a pair of incisions above the middle of each rubber cushion, whereby a better light-tightness between the cushions is attained.

Fig. 1.

Fig. 2.

The apparatus is used in the following manner, it being understood that film envelopes are used of the kind described in Patent No. 120,572.

The cover 4 with the lid 7 is removed and turned over, and the film envelopes are now introduced downwardly between the cushions 5, the tongue of the shutter of the envelopes being first bent up or straightened and then inserted. The tongue of the film envelope shutter is pushed so far through the space between

Fig. 3.

Fig. 4.

two cushions, that the back and holding strip of the envelope are stopped by the cushions, which pinch the envelopes.

When the cover and lid are turned back into their normal position the tongues will all project upwardly through the lid 7 and the cover 4. Thereafter the developer is filled into the tank, the film envelopes are introduced into the developer, and the cover 4, together with the lid, are placed on the tank, after which the shutters of the envelopes are drawn up, whereby the shutters

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

of the envelopes which are guided in the incisions in the sliding lid 7, are bent on over the cushions, thus securing light-tightness along the edges of the film envelopes by shading the spaces between the cushions and the edges of the films.

As a modification, it may be mentioned that the cushions 5 may be replaced by the guides which are curved longitudinally so as to loosely interfit in the manner shown at 12 in fig. 8. Thereby the sliding cover 7 may be omitted, if preferred.

When the developing has been finished, the tube is removed

from the funnel 3, and is bent downwards to discharge the liquid. Then the tube is again applied on the funnel in order that the fixing bath liquid may be filled in through this.

When the exposed and developed films or plates have been fixed, they must be washed, and this is done in the same tank. For this purpose the cover 4 and the lid 7 are removed, and the films which are taken out from the envelopes are suspended in a clip 9, which is provided with yielding cheeks 10, which clip is placed on the upper edge of the tank, as shown on Figs. 5 and 6, after which water is led through the apparatus, by which the tube acts as an overflow, as the upper edge of the funnel is lower than that of the apparatus.

Owing to the wedge-form of the apparatus its volume is much smaller than that of those in general use, so that less quantities of chemicals are employed, and by using film envelopes of the kind referred to, perfect light-tightness during developing may be secured.

It should be mentioned that for the washing of plates there may, in known manner, be used an inner frame or stand instead of the clip 9.

The funnel 3 and the tube 2 need not be outside, but may, both for filling and for washing purposes, be replaced by an inner cross wall with holes near the bottom, or which does not reach entirely down to the bottom, in which case the top edge of the outer wall of the apparatus, which corresponds to the cross wall, is made lower than the other outer walls.—Jens Peter Hensen, 10, Jacob's Allé, Copenhagen, Denmark.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

PERMALYNE.—No. 392,736. Photographic and drawing office prints on linen. Lawes Bros., Ltd., 7-9, Burrup Place, Doris Street, Kennington, London, S.E.11, photographic printers and drawing office stationers. June 26, 1919.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, SEPTEMBER 27.

Chelsea Photographic Society. Outing: A River Walk.
St. Clements Press Photographic and Rambling Society. Outing to Edgware and High Barnet.
Hackney Photographic Society. Outing to Sewardstone.

MONDAY, SEPTEMBER 29.

South London Photographic Society. "Sketch Portraiture." H. C. Inskeep.

TUESDAY, SEPTEMBER 30.

Leith Amateur Photographic Association. Annual Business Meeting.
Manchester Amateur Photographic Society. Demonstration.

WEDNESDAY, OCTOBER 1.

North Middlesex Photographic Society. "Combination Printing." H. W. Fincham. Special Print Competition: A Street Figure Study.

THURSDAY, OCTOBER 2.

Hodley and District Photographic Society. Monthly Competition: "Fowls."
HammerSmith (Hampshire House) Photographic Society. "Vignettes of J. M. W. Turner, R.A." C. W. Philpot.
Liverpool Amateur Photographic Association. "Through Iceland on Ponyback." Rev. J. A. McIlvoride.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Hon. sec., 5a, Pall Mall East, London, W.C.1.

October 13 to November 29.—Royal Photographic Society.—Entries close September 19 (carrier), September 20 (hand). Secretary, J. McIntosh, 35, Russell Square, W.C.1.

A PERSONAL LINK with the past of the British lens-making industry is broken by the death, announced on Wednesday last, of Elizabeth Mary, widow of John Henry Dallmeyer, who died on September 22 at Hampstead, aged seventy-one.

Commercial & Legal Intelligence.

AT CHORLEY COUNTY COURT, on September 18, David Glazier, photographic artist, trading as D. Henries, of Cheetham Hill, Manchester, sued J. Walton, of Leyland, for £4 10s., the price of an enlargement. Delivery was admitted, but defendant contended that the reproduction was nothing like him. A verdict was given for £3 10s.

LEGAL NOTICES.—Notice of intended dividend has been given in the estate of Arthur Aquila Noakes, photographer, residing and carrying on business at 17, St. Peter's Street, Canterbury, and lately carrying on business also at 29a, St. Margaret's Street, Canterbury. Proofs must be lodged on or before October 1 with Mr. J. Osborne Morris, Official Receiver's Office, 68a, Castle Street, Canterbury.

NEW COMPANIES.

BOURNEMOUTH PHOTO ENGRAVING Co., LTD.—This private company was registered on September 15 with a capital of £2,000 in £1 shares. Objects: To take over the business of photographic engravers carried on at Albert Road, Bournemouth, as the Bournemouth Photo Engraving Co., and to enter into an agreement with R. S. Holditch. The subscribers (each with one share) are: A. W. Evans, 1, Esmond Road, Bedford Park, W.3, journalist; S. L. Barber, 42, Carden Road, Peckham Rye, S.E.15, newspaper manager. The first directors are: Major W. J. B. Evans, Bod Ivan, Llandinam; A. W. Evans, S. L. Barber and R. S. Holditch (293, Wimborne Road, Winton, Bournemouth). Qualification: £1. Secretary: F. H. Harman. Registered office: Observer Chambers, Albert Road, Bournemouth.

News and Notes.

THE KING AND QUEEN honoured Mr. Vandyk with a special sitting for their photographs at Balmoral.

BEACH PHOTOGRAPHY.—When caught on Blackpool sands with photographs, Arthur Atterbury (photographer) told the constable he was just "trying to earn his fine for to-morrow." He was summoned for the offence at the Police Court, when it was said he had been fined three times for similar offences. He had to pay 40s.—Harry Marks, a travelling photographer, was on September 19 fined 40s. for selling photographs on the foreshore. The Chief Constable said defendant was one of the usual crowd. They knew what they were doing.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—A general meeting of the Society will be held on Tuesday, September 30, at the Queen's Hotel, Promenade, Southport, at 3.30 p.m. The committee will meet on the same day at 2.30 p.m. A social evening will follow the general meeting, and it is hoped that every member of the Society will attend on this day. Ladies are specially invited. Those members who wish to make a full day's outing, and who desire a morning's golf, should communicate immediately with the hon. treasurer, Mr. F. Read, 14, Balfour Road, Southport, who is in charge of the local arrangements.

MR. HAROLD E. MARSHALL, enlargement specialist, of Mansfield Road, Nottingham, has formed a partnership with Mr. Cecil Higson, formerly of the London Photo-Centre, Royal Air Force. Messrs. Marshall and Higson will trade together as Marshall and Company. The firm's price-list of enlarging and other trade work which has just been issued specifies the charges for straightforward enlargements and for water-colours and sketch portraits. A specialty is also made of retouching at photographers' prices. Mr. Marshall has long enjoyed a large measure of appreciation for the excellence and reliability of his trade service, and we have no doubt that the latter will be fully maintained under the extended management.

A CITY SALE NUTSHELL COMPETITION.—The City Sale and Exchange announce a competition in which prizes to the total value of £20 will be awarded for the best phrases of four words the initials of which are those, C S A E, of the name of the firm. The "nutshell" phrases are required to express some aspect or opinion of the

City Sale's business. There are no entry fees or conditions of any kind except that a competitor may send one entry only and must send it on a form (to be pasted on a postcard), which is obtainable at any of the establishments of the City Sale and Exchange, or is sent post free on request. Sufficient time is allowed for entries from overseas, the last date for Colonial and foreign entries being November 21. The prizes offered are five guineas, three guineas, and two guineas, for the first, second, and third best phrases, together with consolation prizes ranging from 2s. 6d. to 15s.

END OF SUMMER-TIME.—The Home Secretary gives notice that summer-time will cease and normal time will be restored at 3 a.m. (summer-time) in the morning of Monday next, September 29, when the clock will be put back to 2 a.m. All railway clocks and clocks in post offices and Government establishments will be put back one hour, and the Government requests the public to put back the time of all clocks and watches by one hour during the night of Sunday-Monday, September 28-29. Employers are particularly recommended to warn all their workers in advance of the change of time.

The public are cautioned that the hands of ordinary striking clocks should not be moved backwards; the change of time should be made by putting forward the hands eleven hours, and allowing the clock to strike fully at each hour, half-hour, and quarter-hour. The hands should not be moved while the clock is striking. An alternative method, in the case of pendulum clocks, is to stop the pendulum for an hour.

PROCESS INSTRUCTION IN MANCHESTER.—The printing department of the Manchester Municipal College of Technology is now under the direction of Mr. R. B. Fishenden. In addition to courses of instruction in typography, machining, lithographic printing and book-binding, photo-mechanical processes occupy an important position. The department includes provision for theoretical and practical instruction in the various branches of photo-engraving, including the making of line and half-tone blocks, three-colour work, photolithography, and photogravure and rotary photogravure. Mr. Fishenden is the lecturer on these photo-mechanical processes and the superintendent of the courses of practical instruction. The work of the department begins on October 6 next, but students are invited to make their arrangements for classes not later than Friday, October 3. A reunion and concert has been arranged to meet old students, members, and other craftsmen returned from war service and will be held at the College on Saturday evening, September 27. Those desirous of taking part in this function should communicate with Mr. Fishenden without delay.

PHOTOGRAPHIC CLASSES AT MANCHESTER.—We have received the prospectus of the part-time classes in the department of photographic technology of the Manchester Municipal College of Technology. The classes in this department, of which Mr. Charles W. Gamble, O.B.E., late R.A.F., is the head, are arranged to provide a systematic course of instruction in the principles and practice of photography extending over three years; but special classes may be attended by arrangement with the head of the department. Two fully equipped photographic studios are available for instruction and practice in portraiture by daylight and artificial light, and the department also includes a cinematograph studio for experimental work, a photo-printing room, and a well-equipped laboratory for research work. Fees for individual classes are 12s. 6d., one night a week, but a great reduction in fees is made when a student takes three or more classes in the course of each week. The session opens on October 6, but intending students should enrol themselves during the week beginning Monday next, September 29. There must be many of our readers within easy access of the Manchester College to whom these courses of instruction provide a most valuable means for systematic and intelligent study of photographic theory and practice.

INTER-CLUB COMPETITION.—Keen interest has been aroused by the Photographic inter-club competition for the "Toulmin" Silver Shield, taken part in this year by fifteen societies, chiefly in Lancashire. The president of the Alliance is Mr. J. Hey, of Colne, and the secretary Mr. A. Clayton, of Blackburn. Darwen Society have again carried off the shield in the print section, this being the third successive year. Preston Pictorial and Chorley Photographic have also been winners on three occasions, but not successively. Mr. Alex. Keighley, F.R.P.S., of Steeton, was the judge. Darwen this year have gained 72 marks. Blackburn coming second with 67, and Nelson

and Preston C.C. following with 63 marks each. The following are the awards:—

Club.	Print.	Mount.	Marks.
Darwen P. S.	45 ...	27 ...	72
Blackburn C. C.	40 ...	27 ...	67
Nelson C. C.	37 ...	26 ...	63
Preston C. C.	38 ...	25 ...	63
Nelson P. S.	37 ...	25 ...	62
Colne C. C.	33 ...	27 ...	60
Horwich A. P. S.	34 ...	21 ...	55
Todmorden P. S.	25 ...	26 ...	52
Preston Scientific Society...	16 ...	25 ...	41

Special prize, best print, Mr. R. Berry, Horwich.

In the slide competition, for which the trophy is the Clayton Rose Bowl, Colne C.C. beat Darwen by 55 points to 53. The slides were judged by Mr. Jas. Shaw, F.R.P.S., of Manchester, whose awards were:—

	Marks.
Colne C.C.	55
Darwen P.A.	53
Mechanics' C.C., Burnley	52
Preston Scientific Society	46
Preston C.C.	45
Nelson C.C.	43
Todmorden P.S.	37
Blackburn C.C.	29

The eleventh annual exhibition of the Alliance is being held at Colne Free Library on October 4.

The special prize for the best slide was won by Mr. T. Plews, of Nelson C.C.

BRITISH LENS MAKERS.—A very sweeping statement disparaging British lenses in comparison with those of Germany and Austria having recently been made in *The Times* by Sir Robert Hadfield, Messrs. Ross, Limited, in a letter which appeared in *The Times* on September 18 last have very properly challenged the views of Sir Robert Hadfield, and have asked for information as to the expert opinion which prompted his statement. We reprint portions of Messrs. Ross's letter:—

"In *The Times* of September 11, under the report of the 'British Association' and the heading of 'Glass-Makers' Ordeal,' you gave publicity to some remarks by Sir Robert Hadfield, which in the interest of the British optical industry, must not pass unchallenged. Sir Robert said:—

"He regretted that we were still dependent on Germany and Austria for lenses of the best quality. His expert friends told him that we still had to go abroad for the best lenses, and the best lenses in his own works were of foreign make. He had given the English makers every chance to submit lenses of equivalent quality, but without a really satisfactory result."

"If these remarks were strictly true, one could only accuse Sir Robert of lack of wisdom in providing our German competitors with an unsolicited testimonial. There is, however, evidence ready to hand which proves conclusively that the facts are not as stated, and therefore one must assume that Sir Robert has been somewhat unfortunate in his choice of expert friends, or that he has not consulted enough of them.

"Captain C. G. Hetherington, R.A.F., Photographic Section, in a letter to the *Photographic Dealer*, says:—

"With regard to the question of superiority of British lenses, I feel a statement upon this point will be of interest to the photographic trade generally. Practically all the lenses used in the R.A.F. for aerial photography have been designed in England during the war for this special purpose.

"From fair comparative tests which have been made these have been found to be superior to any enemy lenses, including those of Zeiss and Goerz, which have been used in the German Air Service. That is a fact. I am not talking sentiment."

"Surely these opinions are sufficient evidence of the trend of general opinion. Possibly Sir Robert refers to a particular type of lens used for some special purpose, and it is conceivable that such a lens might not yet have been manufactured in this country with the same success as in Germany, but this does not by any

means justify so sweeping a statement as Sir Robert makes. Speaking of the lens industry as a whole, we have undoubtedly not only caught up the German manufacturer, but have in many cases surpassed him.

"It would, at any rate, be interesting to know the source of the expert advice which has led Sir Robert Hadfield to make this statement, which can be nothing else but injurious to the British optical industry."

Correspondence.

NATURAL COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—My attention has been called to an article in your columns on the above subject. I would like to mention that I am also interested in a process of colour photography, apparently in every way similar to that described in your article. I notice, however, the date of the patent application for the process described in your columns is given as January, 1919, whereas my process is patented as and from March, 1918, nearly twelve months previously. This specification also describes the taking of pictures without the use of colour-screens. I may add that the process has been proved a success, and in a short time, I hope, will be on the market entirely with the aid of British capital.—Yours faithfully,

London, W.C.1

J. SALTER.

EYEGLASS FOCUSING MAGNIFIERS.

To the Editors.

Gentlemen,—My point is that "Bifocal" is not getting what he thinks he is—i.e., an image of the same subject on the fovea of each eye at the same moment—for it is incredible to me that anyone not suffering from bilateral convergent strabismus of a most pronounced type could do this at a distance of 3 in. It must be very painful, even if possible, to anyone else!

It may be worth while having spectacles made as he suggests—I do not know, and should hardly think so; but they will not give binocular vision.—Yours truly,

TRAVERS J. BRIANT.

Beverley, Epsom, September 20, 1919.

To the Editors.

Gentlemen,—I think "Bifocal" must be in error with regard to his bifocals. Either they are not so powerful as he thinks, or else he does not get binocular vision. It is easy to see that to maintain single binocular vision with lenses having a focal length of "under three inches" it is necessary to converge each eye about 25 degrees.

If they are really of that power, it is more likely that he is using one eye only, and mentally suppressing the image given by the other—a habit quite easy to acquire.

The best advice I can suggest to anyone who wishes to follow "Bifocal's" advice is to explain the requirements to an optician and be fitted with the most powerful lower segments possible, consistent with maintaining single binocular vision.

If "Bifocal" cares to send me his lenses through the Editors I would tell him their power and return them immediately.—Yours faithfully,

A. G. WILLIAMSON, F.S.M.C.

37, Hinstock Road, Plumstead, S.E.

September 22.

A COMMON CAUSE OF LOSS OF BUSINESS.

To the Editors.

Gentlemen.—In my observation, one of the commonest causes of loss of custom by photographers is unreasonable delay in the execution of orders. At an establishment employing about a dozen hands that I visited some two or three years ago the proprietor showed me letters of bitter complaint and angry reproach from customers whose orders had been in arrear for some time, and he told me that he was receiving such letters nearly every day, and did not know how to remedy it. I then explained the plan which I had followed in my own business, and he at once adopted it, together with a reorganisation of the printing arrangements.

Down the centre of the page in the day-book a line is ruled in red ink across each order as it is despatched to the customer. When all orders on the page are completed, the line is continuous from top to bottom. Turning back a few pages, any break in the line shows that immediate attention is required.

The printer's order book is treated similarly, except that a pencil line is here considered sufficient.

W. E. DEBENHAM.

AMATEURS' FILM SPOOLS.

To the Editors.

Gentlemen.—I have been particularly impressed this summer by the number of amateur customers who have come into my business with spools of film which have not been the right size for their cameras. It seems such a pity if a photographer or chemist lays himself out to cater for amateurs at all that he does not take particular care to teach his assistants the different sizes, and make them note the name and size of cameras brought in. Only to-day I had a young man bring in his camera who said he had been winding off the film from the spool he had purchased on to another spool to fit his camera. I told him he must have been supplied wrongly, and he said he got the spool at a local chemist and was served by a "bit of a young girl." I found his camera was a No. 2 Ensignette, and he had been supplied with a V.P.K. spool. I may say that my assistants have been so drilled on sizes that they rarely give a wrong spool, and if in doubt always go to me or a senior assistant. Even my "bit of a girl," though only 15, has been thoroughly taught. It is really quite easy to master the sizes if one will only exercise one's memory. The mention of a size immediately suggests the number on the spool, viz., $3\frac{1}{4} \times 2\frac{1}{4}$ suggests No. 120 or 105. There is only to find out if the camera is a No. 2 Brownie or a No. 1 F.P.K., and then the proper film is easy enough to find. I don't think photographers realise that amateurs are at all profitable if properly catered for. I find that amateurs very often know quite as much as professionals, and also a great many films and plates are spoilt in developing carelessly done. To my mind, if this branch is worth doing at all it should be done properly, and not pushed off with "Oh, it's only an amateur, they won't know." Some amateurs are very stupid, of course, but most of them are only so because the people they buy cameras from won't trouble to show them how to use it, or take any interest in them.—Yours faithfully,

ALICE O. YARDLEY.

197-198, High Street, Gorleston-on-Sea.

THE "CROYDON" HECTOGRAPH.

To the Editors.

Gentlemen.—Although the hectograph, strictly speaking, is not a true photographic article, particulars of it may legitimately find a place in your columns because of its usefulness to secretaries of photographic societies, and your Croydon reporter is to be congratulated upon his helpful report and, further, upon spelling the name of the article as he has done, for the word "hektograph," commonly used, is a very ugly one. Some may argue that the latter is the more correct, but in my humble opinion both are very unfortunate names for an article that fails to give one hundred copies, as either name leads one to believe it to do.

Hectographs, or "jelly-copiers," of the ordinary type are composed of gelatine and glycerine, with a preservative—usually oil of cloves; but the golden syrup Mr. Purkis gives in place of glycerine is a decided improvement. One has an idea, somehow, that golden syrup was used in place of glycerine because of the scarceness and high price of the latter during the war. Be that as it may, I feel sure that makers of a hectograph will find syrup to be very much better than glycerine.

One hears complaints sometimes about the discoloration of the jelly owing to the absorption of the dye-ink, which can never be cleared off properly. The way to get rid of the discoloration and to clear the jelly is to remelt over a slow fire or in a warm oven, and then stir in a little dried whiting; the latter appears to take up the dye and settle at the bottom, leaving the jelly-bed fairly clear.

I wish your Croydon reporter had not dealt with inks so briefly, as inks are most important. The best black ink I have used is to mix 1 oz. methylated spirit, 1 oz. water, 2 oz. glycerine, 60 gr. aniline black (soluble in water), and warm and stir till the colour is quite dissolved; for other colours use a suitable aniline dye in place of the black. I am, however, grateful to your correspondent for the methyl violet ink formula, which I hope to use, having failed, so far, to get a good home-made violet preparation, in spite of the many formulæ that have been published.—Yours faithfully,

L. T. WOODS.

PHOTOGRAPHERS AND THE SALE OF POSTCARDS.

To the Editors.

Gentlemen.—Christmas is drawing near and photographers throughout the country, having finished their summer trade, are looking for something to liven them up during the winter months.

The real-photo postcard trade is with many photographers a "side line," because they look upon the 2d. or 3d. postcard as *infra dig.* in comparison with their high-class studio work, and they leave it to the local stationer. This may be quite good in a way, but most photographers have among their negatives—hidden away—numbers of interesting subjects—local views, churches, country houses, portraits of local celebrities, clergy, warriors, public men, pretty children—in fact, there is no end to the variety of subjects which a country photographer has on his shelves, which during the busy season he has not had time to even look at. These subjects are not generally known to the stationer who buys from the postcard publisher's stocks, and as these stocks are produced in large quantities the number per negative is more than the publisher can afford to purchase, owing to the limited sale of such pictures.

If the photographer would look out these negatives, and if he has no time or convenience to print them in his own studios, send them to a trade printer, order, say, 1 gross of each subject, and exhibit in his window a sample of each subject nicely mounted on a show-card with suitable artistic wording, I venture to say that he would create a profitable trade and bring customers into his studio for other work. If he orders from a trade printer the cost of one gross per subject is 16s., and he sells at 2d. or 3d. each. This makes a profit of 50 per cent. to 125 per cent. on outlay without risk of heavy stock. This cannot be done by the stationer, who has not the negatives.

I should like you to find space for this letter in order to bring home to the photographer the possibilities of increasing his prospects without any trouble to himself or employees, as apart from profit on sales, he would advertise his business.

I can hear the following drawing-room conversation:—

"Mr. Enterprise has some beautiful postcards of _____ in his window, let us buy them for Christmas cards. I will call and ask what he would charge to take our house and do a hundred or two postcards. They are awfully good."

Then the photographer gets an additional order.—Yours faithfully,

PHILIP G. HUNT.

332, Balham High Road, London, S.W.17.

September 23.

SELECTIVE REDUCTION WITH BICHROMATE.

To the Editors.

Gentlemen,—Some years ago I made a series of experiments with bichromate-hydrochloric, both as a reducer and an intensifier. Unfortunately my notes on this subject are all abroad at present, but your article on reducing (p. 539 of September 12) reminds me of the subject.

So far as my memory serves me, I used a solution composed as follows:—

Potassium bichromate	10 gms.
Water	1,000 cc.
Hydrochloric acid	2 or 3 drops

I wished to get more contrast in an over-dense negative and to reduce the shadows. If a negative is immersed in the above solution it will be noticed that the bleaching takes place evenly downwards, the thinner part, i.e., shadows, being the first to be entirely pene-

Fig. 1.

trated and finally the high-lights, the reason being that the thickness of the silver deposit is greater in the high-lights than in the shadows. The diagram (fig. 1) will assist in making my meaning more clear. It is an enlarged section of which the shaded portion represents the silver deposit of the negative. The bleaching will have passed successively through the layers 1, 2, 3, 4, 5, 6. If, however, the bleaching is stopped when it penetrates to layer 3, it follows that down to layer 3 the silver will have been transformed into a chloride which is soluble in hypo, and the remaining layers, 4, 5, and 6, will be insoluble silver and not affected by the hypo (fig. 2).

Fig. 2.

If at this stage the partly bleached negative is washed well and then put into hypo all the silver in layers 1 to 3 will be dissolved out and the remainder, 4, 5, 6, be unchanged, i.e., the high-lights slightly reduced in density will remain, also part of the shadows, and the result will be a more brilliant negative as in fig. 2. If, on the contrary, I wish to decrease the contrast in a negative, I bleach the negative entirely through, then wash it well and re-develop it with a weak metol-hydroquinone developer. Now the re-development takes place exactly in the same way as the bleaching, i.e., penetrating evenly downwards by layers, so that if I re-develop down to No. 4 layer fig. 3 will be the result. If now I put this into the hypo,

Fig. 3.

layers 1 to 4 will remain insoluble, and layers 5 and 6, being soluble chloride, will be dissolved out. The negative will therefore have less contrast. The operation should be carried out in the dark-room, as the bleached negative is sensitive to light. It is as well to experiment on some old negatives, as it is somewhat difficult to judge the exact amount of bleaching.

Trusting this will be of use to some of your readers, yours, faithfully,

E. G. SIMPSON.

7. Clinton Hill, Dormans, near Lingfield, Surrey, Sept. 13.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. H.—We think you come under the Retail Businesses Licensing Order, and require to apply to the regional headquarters at Iddesleigh Mansions, Westminster, London, S.W.1.

T. AND CO.—The query is too general to be answered briefly. You will probably find all the information you require on fitting half-watts in an article which appeared in the "B.J." of October 26, 1917, which our publishers can supply price 4½d. post free.

H. W.—No licence for the business you mention is required in either case, presuming that the business is carried on in such a way that the general public in the neighbourhood will not be able to discover it in the way that they can discover goods for sale in an ordinary shop. If the business offers work to the public as a shop offers goods, then we think we think it comes within the Retail Businesses Order, and in that case you require to have a licence.

W. T.—Gaslight prints are quite as permanent as bromide prints. In the case of either paper the warm tints obtained by development are not as permanent, in our opinion, as the ordinary black tone. A silver image obtained in the more finely divided state which represents a warm colour is, as a rule, more susceptible to the action of damp, gas fumes, etc., than is the coarser black image. On the other hand, a print which is toned by bleaching and passing through a sulphide bath is more permanent than a black print.

A. E.—The bracket in your studio has probably been placed there to support an enclosed arc lamp, and would be of little use for half-watt lamps which require to be distributed to give the best effect. It is much better to have them to raise and lower. Each lamp will require a reflector and diffuser, or you might arrange a thin calico curtain in front of them all with an opaque reflector, dark on the camera side and white towards the lamps. These could be hung on rods not too near the globes, or the material will be scorched.

N. W.—It is possible that under the Retail Businesses Licensing Order you require a licence for starting a business which has been suspended, but bear in mind that the Order is made for the purpose of protecting men like yourself who have been in the Services, and whose businesses have been temporarily closed on that account. You should have no difficulty in obtaining a licence to re-start in the present premises, and equally if you move the business to another address. You should apply to the regional licensing headquarters at 5a, Union Street, Bristol.

M. N.—We think you refer to the paragraph on p. 262 of the "B.J." of May 18, 1917, contained in an article on washing, by A. W. Warwick, where it is stated that an osmotic pressure of 210 lb. per square inch is produced when a hypo-saturated film is placed in water. We are sorry we are not able to say whether such a figure is approximately correct. Without professing to know very much of the physics of surface tension or osmosis phenomena,

we should doubt whether your theory of pinholes being caused by disruption of the film through air-bubbles on it during washing accounts for the effects.

V. C.—Most Press photographers use a plate not of the very maximum speed, but one such as Imperial Special Rapid, although an ultra-rapid plate, such as Ilford Monarch or Marion Record, will be used as occasion requires. For such quick movement as is met with in ordinary street scenes and functions apart from sporting subjects, 1/50th second is as rapid a shutter exposure as is ever necessary, usually a very much slower speed is all that is required. The best place at which to have your shutter tested is the National Physical Laboratory, Teddington. A good developer for strong negatives is the Imperial pyro-metol.

A. S.—There are several text-books of colliotype, but we think the only one in print is "Photo-Mechanical Processes," by W. T. Wilkinson, price 4s., from Messrs. Hamptons, Cursitor Street, London, E.C.4, which deals also with other photo-mechanical methods. Apparatus such as drying ovens and presses are supplied by Messrs. A. W. Penrose and Co., Ltd., 109, Farringdon Road, London, E.C.1. No book instruction would enable anyone quite inexperienced to learn the process; he would require a course of practical instruction, the best place for which is the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, London, E.C.

J. R.—As you have sketched your diffusing screen at right angles to the background and 6 ft. away, it would seem that you would waste a good deal of light and, what is worse, have a glare between lens and sitter. To get the greatest advantage with these lamps it is desirable to arrange them slantingly across the studio, one being nearly in the middle about 8 ft. high and 8 ft. from background and the others in a curve to one side, the two ends being rather lower, say 6 ft. from floor. If you decide to keep to your sketch we should place the four lamps in pairs, two 8 ft. high and 4 ft. apart and two 6 ft. high and 3 ft. apart, these two being rather nearer the sitter's end of the screen.

O. P. C.—Water-soluble Nigrosine can be obtained from any of the merchants in fine chemicals, such as Messrs. Harrington Bros., 4, Oliver's Yard, City Road, London, E.C., price about 1s. 6d. per ounce. About the best preparation for backing is a mixture of caramel brown or black pigment, such as burnt sienna or vegetable black, gum syrup, and methylated spirits. The caramel should be the special kind made by Lichtenstein, for backing, and can be obtained from dealers in photographic chemicals, such as Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C. For ordinary plates the reddish pigment, such as burnt sienna, can be used, but for colour-sensitive plates it is better to use a black pigment. Simply dissolve the caramel in the minimum quantity of water thickened with the strong gum solution, and add enough spirit to make the mixture quick drying.

T. G.—To secure short exposures and soft even lighting you will require about three 1,000 c.p. half-watt lamps. These may be conveniently fitted in a curve, the first being opposite the centre of the background about 8 ft. from the ground, the others generally approaching the side of the studio, that nearest the background being rather lower, say, 6 ft. from the ground. If possible make them all to raise and lower, as this will enable you to make shorter exposures with sitting figures and children. Each lamp should have its own reflector and diffuser and work from a separate switch, thus obtaining full control of the lighting and economy of current. A round head screen and a reflector of the usual type are all the appliances required. You should make sure that your current is actually of the voltage it is supposed to be, as running the lamps even slightly under their full voltage will cause a considerable loss of actinic power.

F. D.—With regard to cost of half-watt installations, we regret we cannot give you any precise estimate, as the prices fluctuate very much just now. There has been an increase of 50 per cent. plus 25 per cent. during the current year on some lines, but we do not think that the lamps themselves have risen to this extent. If you write to the General Electric Company, Ltd., 67, Queen Victoria Street, London, E.C., stating your exact requirements they will send you an estimate which would probably hold good for a few days. We cannot advise you with regard to the wiring, as we do not know the capacity of your leads nor the voltage of your supply. Your local electrician will be best able to judge.

If your place is only wired for a few lamps, heavier leads will probably be necessary, but this should not be expensive to instal. At present portable studios are fetching about three times pre-war prices, so that we should advise you to use the room which would also be more comfortable in winter.

REX.—For enlarging a 6 × 5 negative three diameters, that is to 18 × 15, with a 7in. lens, the space required between the negative and the paper is just under 3 feet, so that you have plenty of room within your 6ft. space for the lantern body. For enlarging smaller negatives up to 15 × 12 you would require more space, but allowing 18 inches for the lantern body and the support of the easel, you could still enlarge 6 diameters with the 7in. lens, that is to say you could enlarge to 15 × 12 from negatives as small as about 2½ × 2 inches. One of the best models of enlarging lantern is the chain and sprocket model of Butcher's. As regards light, apart from ordinary central draught oil lamps (which would be very difficult to fit to the ordinary lantern body) the only lamp is the "Lana" incandescent mantle lamp of W. C. Hughes and Co., 82, Mortimer Road, Kingsland, N.1., burning methylated spirit. In hot weather it will make such a very small dark-room uncomfortably warm, we think, but otherwise is an excellent lamp.

SENSITIZING CANVAS.—I should be obliged if you could tell me where, or how, I could get enlargements from my own negatives lightly printed on my own canvases. Any rough indications of the subjects would suffice as long as they saved (sometimes difficult) drawing, placing, etc., of such details as jewellery on the work. I imagine that such a thing as a bromide solution might be lightly brushed on the required spot, and be developed and fixed with a large, soft brush, sufficiently plain to work on. Some particulars of this might be of interest to many "B.J." readers.—ALPD. J. N. GOODSON.

A process of sensitising canvas for enlarging is what you want, and was much used years ago before bromide paper became so largely used in the cheap enlargement trade. We gave a large number of these sensitising formulæ in the "B.J." of August 25, 1916 (price 4½d. post free from our publishers). No doubt you can work the process yourself if you have facilities for enlarging with an light, or even a light of lower power if you are content with mere outline sketches.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepared, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.

Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In consequence of the railway strike, and as a precautionary measure towards attempting to ensure regular publication, a number of articles, paragraphs, etc., are held over.

The first instalment of a paper, read before an American Convention by Mr. Herbert G. Stokes, deals with various time-saving devices in photographers' work-rooms and includes (this week) general arrangement of a printing-enlarging room, making of multiple vignette prints and introducing diffused focus into prints from normal negatives. (P. 575.)

In a leading article we describe the effects noticed as regards fading in a batch of prints which by accident had been stored for about a year in a very damp place. Platinum prints were the only ones which were absolutely unchanged. (P. 574.)

In his article this week "Practicus" deals with the photography of wedding groups. He gives hints on the general arrangement of the figures, selection of background, development, and on the style of mounting most generally preferred. (P. 577.)

An aid to writing titles on negatives so that the letters are reversed as regards right and left is provided by the hectograph method of duplicating copies. (P. 574.)

The making of diagram enlargements for school use is a branch of work for which in some places a demand may be created. (P. 573.)

Protective coatings for dishes require to be selected in reference to the solutions which are being used. Shellac varnish is unsuitable for any solution, such as a developer, which is strongly alkaline. (P. 574.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

MM. A. and L. Lumière and A. Seyowitz communicate a simplified method for the development of Autochrome plates. It is a method based on the observation of the time of appearance of the image in a diluted developer, the plate being transferred to a stronger solution as soon as the image has appeared. The dilution of the first and second developer is adjusted so that the plate is developed in the second for the same time as was required for the image to appear in the first. (P. 37.)

Details are given in a recent specification of Mr. F. E. Ives of a method of producing two-colour prints or films, a salient feature of which is the combination of a red copper-toned silver image with one of blue-green colour, preferably formed by means of iron toning. (P. 38.)

Some practical hints on the use of colour-screen plates refer to exposure and to the somewhat different requirements in this respect of the Autochrome and Paget plates. (P. 40.)

Mr. E. G. Handel-Lucas, writing on the future of three-colour photography, urges that a return is necessary to its first principles, and also that consideration deserves to be given to the incorporation in any three-colour system of working of a key-plate in black or grey corresponding with an alleged perception of neutral tone differences by the eye. (P. 39.)

EX CATHEDRA.

Mixed Lighting.

Now that the days are becoming appreciably shorter, those photographers who have suitably arranged artificial lights will find a considerable advantage in using them to supplement poor daylight. In many cases this is not possible, as the lamps are fixed on the solid side of the studio to avoid interference with the working of the blinds, but if there happens to be a lamp fitted to a movable stand or pedestal it can easily be moved into a position where it will give the necessary "snap" to the lighting. Used in this way, it allows of the figure being lighted rather flatly by opening the blinds to almost their full extent, the electric lamp being used for the production of high lights. A few experiments will probably be necessary to hit the correct exposure, since there is hardly any form of artificial light which is exactly the same colour as daylight, the enclosed arc appearing bluer and the nitrogen-filled lamps more yellow. In any case the difference in lighting will not be great, even if the colour be not allowed for. This expedient has in some hands proved very useful for child portraiture in the winter, even when the daylight was fairly good, as it allowed of much shorter exposures being made than was possible with either light used alone.

* * *

Enlarged Diagrams.

We recently saw a number of diagrams which a teacher had enlarged upon bromide paper to a uniform size of 20 x 16. He said that their preparation had saved an enormous amount of black-board work, and, being sharper and more accurate, were much better for the purpose of instruction. This would seem a class of work that photographers who make their own enlargements might profitably take up. The negatives should be made upon process plates, and if carefully exposed and fully developed will need no intensification. A slow bromide paper and well-restrained developer should be used to ensure good clean lines. Any slight deposit on the whites can easily be cleared off with Farmer's reducer or iodine and cyanide solution. The photographer's work might end here, leaving the mounting on calico or board to the teacher. In order to keep the surfaces clean—no easy task in a school—the prints should receive a coating of clear "paper varnish," such as is used for wall decoration, this also serving to prevent sulphurisation. If any colouring is needed it can easily be done before varnishing, and as there is already a coating of gelatine no sizing is needed. This method might also be extended to the reproduction of tables of figures, where hand copying would necessitate great care and require checking by an expert.

Stale Solutions.

Many otherwise inexplicable variations in the quality of negatives and prints may be traced to the use of stale chemical solutions. We recently came across a bottle of concentrated pyro solution made about three months previously. The usual preservatives, sulphite of soda and metabisulphite of potass, had been used, but the developer worked very slowly, and after double the usual time of immersion the image was still too thin to yield a good print. As an experiment double the quantity of pyro solution was put in to the same quantity of water as in the first trial. This developer yielded quite a satisfactory negative in the usual time. Shortly after this a friend showed us a bottle of a well-known single-solution developer which had been left uncorked for over two months. It had turned very dark and somewhat turbid. Upon trial it worked much more slowly than it usually did when diluted to the normal extent, but upon adding about 50 per cent. more of the concentrated solution it behaved in its usual manner. It is perhaps not often that it is necessary to use stale developer, but if one is in that position it is useful to remember that the difficulty may usually be surmounted by using rather more of the stock solutions. Of course, if a developer made up to working strength has deteriorated there is no other course than to use a liberal quantity and give a prolonged development. If this fails, nothing else can be done but to make up fresh solutions.

* * *

Coatings for Dishes.

The high prices now charged for large dishes in vulcanite, enamelled iron, or porcelain have caused attention to be directed to substitutes made of wood. These, of course, require some coating to render them non-absorbent of the solutions used, and many recipes have been given for this. It is obvious that the purpose for which the dish is to be used must be taken into consideration, as coatings which are quite suitable for one class of solution may be soluble in another. Shellac varnish is often recommended, and is quite useful for washing-trays or with solutions having an acid reaction. It could, for example, be used for developing enlargements with amidol to which a little metabisulphite has been added, but not with a metol-hydroquinone developer, which contains enough alkali to soften and ultimately to dissolve the coating. One of the best methods of lining a dish is to use brown linen holland, which should be carefully glued in. When quite dry, paraffin wax is applied by means of a hot flat-iron, taking care to saturate the fabric and to fill any creases in the corners. This will resist any solution likely to be used in photography, and as soon as any sign of wear appears a cake of wax and a hot iron will give the dish a new lease of life.

* * *

Transferring Titles.

Few people who have not been trained as lithographers have the knack of lettering in a reversed position, and we frequently see postcards and other prints which are spoiled by having a clumsy, ill-written title printed upon them. Those who wish to make neat titles may borrow a useful hint from Mr. Purkis's recent lecture at the Croydon Camera Club. The negative film when wet is very receptive of aniline dyes, or even of ordinary copying ink. All that is necessary is to draw the lettering carefully upon very hard paper with a pen and ordinary violet or red ink. As no copies are required the thick hektograph ink is not necessary; indeed, it is best not to use it, as it may spread in the film. While the ink is drying the negative is well damped until the film is swelled in the desired spot, after which the written title is laid upon it face down, and gently rubbed into contact. It should be left for about half a minute and then stripped off, when the title will be

found to be clearly impressed upon the gelatine. It will be too faint to print as white, but it can, when dry, be traced over with opaque. It will often be found that after this has been done a few times the appearance of reversed letters will be sufficiently familiar to allow the work to be done directly, that is, without the aid of the transfer.

DAMPNESS AND FADED PRINTS.

THAT there are so many different views held as to the relative permanency of photographic prints is probably due not only to variation in the methods by which the prints have been made, but to the conditions under which they have been kept. When both sets of conditions are favourable a fairly high degree of permanence may be obtained even with silver images, while on the other hand a few weeks or months at most may witness the almost complete destruction of the image.

Leaving out of the question chemical vapours such as might be found in a laboratory, iodine, chlorine, or sulphurous acid, it would seem that there are two main features in the destruction of an ordinary photograph, the sulphurous vapours usually present in town atmospheres and dampness.

We have lately had an interesting demonstration of the action of damp by the discovery of a large number of photographs, embracing examples of nearly all the processes in common use, which had been stored in a cupboard presumed to be dry, but which by the unsuspected leakage of a pipe embedded in the wall was extremely damp at one side. The photographs were of all ages; some albumen prints made over thirty years ago; bromides of all ages from thirty years to three months; some P.O.P. and collodion prints of all dates, as well as a few carbon platinum prints and some three-colour process proofs—all were in this collection. It may be as well to say that, in spite of their age, all the prints were in fairly good condition when stowed away a little more than a year ago. The deterioration, which has in most cases been utterly destructive, is clearly due to the damp atmosphere. The albumenised prints have faded from a good purple to a yellowish brown, the paper also yellowing. The bromides, originally brilliant specimens, have in the case of untuned prints faded almost away, while sulphide-toned ones have lost much of their strength. Prints on collodion papers have faded badly, showing a spottiness not present in the bromides. Only platinum prints were absolutely unchanged. In some cases mildew has formed upon the surface, but when this was removed the image, as was to be expected, was perfectly good. Carbon prints have stood well, except that where mildew has appeared the surface of the gelatine has been spoiled. A curious effect was observable in the prints from three-colour blocks; in some cases the red printing colour had, through the action of the damp, diffused itself all over the surface of the picture, and in some cases through to the back of the paper.

As a contrast to this we have prints made under similar conditions which have been kept in dry cupboards in a gas-lighted stove-heated room which have endured wonderfully well.

It is thus seen, then, that damp is a most potent factor in the fading of prints, and every precaution should be taken to secure silver images from it. In the case of framed pictures it is of little use to paste up the backs of the frames as long as the cardboard and wooden back remain porous and permeable to the atmosphere. It would seem that the safest treatment, as far as permanency is concerned, is to dry-mount the prints with a good shellac

tissue, and to coat the faces either with a varnish or to rub them with a good encaustic paste.

It must not be overlooked that although toned bromide prints have suffered from their severe ordeal they have not done so to the same extent as the black and white ones. In the case of the albumen prints, those toned to a purple have been found to fade less than those of a brown colour.

No oil-prints or Bromoils were submitted to this involuntary test, but it is to be presumed that they would

have stood it as well as a few collotypes which had retained their original freshness. The moral which the professional photographer may draw from this experience is that it is very desirable to keep all showcases and window enclosures well ventilated in damp weather, and that in the case of pictures hanging upon outside walls a couple of corks or studs should be placed at the lower corners of the frame, so as to allow of a current of air passing between the wall and the picture.

EFFICIENCY IN THE WORKROOM.

THERE are too many photographers to-day who pay insufficient attention to workroom efficiency. Some kind of system has to be observed in the office and reception room, but so long as the photographs come through eventually, little thought is given to the methods employed in the workroom.

The processes necessary to the correct evolution of a picture from dark-room to client are so many, and our opportunities for increasing the efficiency of working conditions are correspondingly numerous.

In producing photographs—whether in large or small quantities—in “popular price” work, or work of the highest artistic value, system, applied to the methods employed, will be found a wonderful asset to every photographer who strives after success.

No business can derive a maximum benefit without it, and the more this efficiency is incorporated in our workrooms to-day, the greater will become the capacity of those studios, their output will be larger and better, and an all-round improvement will be the result.

I am not propounding something new. Everyone of us realises the obvious truth of these facts, yet how many of us apply them to the everyday routine of a modern studio?

I am talking to you to-day against my own inclinations. I realise that I could learn from so many of you here much more than I am able to teach. But those in authority at this convention have been good enough to consider that our workrooms are conducted on a system which is helpful, and also that we have in those workrooms a few original ideas which ought to be spread broadcast among photographers, hence my appearance here.

I have no doubt that before this convention is over I shall find that my original ideas are also subjected to that old

Fig. 1.—Efficient arrangement of printing and enlarging rooms.

saying, “There’s nothing new under the sun.” But my efforts are simply directed towards showing what big time-savers and efficiency-makers I have found these ideas to be, and it’s immaterial who discovered them.

My first illustration shows the relative position of the important apparatus in the printing room (Fig. 1). Before I proceed further, let me suggest that if we spent more con-

scientious thought on the arrangement and conveniences of the printing room, 50 per cent. of the photographer’s troubles would be automatically removed. I have heard it repeatedly asserted by men who ought to know, that a good printer is as important an asset as any man in the studio; if this be so, then the room he works in should be treated with equal importance.

The old fallacy that a printing room must necessarily be a dark-room has long since been exploded. Plenty of light is permissible, provided it is safe light, and with light, cleanliness will become an easier accomplishment.

To return to my illustration of the printing room. Emphasis ought to be laid on the fact that there is little or no lost motion, that each consecutive process follows the other in direction as well as order. The shelves for storing paper and the cutting bench comes first, then the printing machine with negatives in order above it—negatives for enlarging, negatives for contact printing, and all negatives finished and awaiting filing. On the right of the printing machine is the up-to-date enlarging machine, whilst the lenses used in enlarging are kept in one section of a sectional bookcase, free from dust and danger of breakage. The developing tray follows the printing—stop bath, fixing, and the large washing tanks complete this “circle of motion.”

The subject of printing could well occupy a talk all its own and still remain inexhausted, but I am just going to touch one phase of the question which ought not to be lost sight of. I refer to the “doctoring of negatives.” What volumes of profanity must have been used to express the thoughts of printers towards the poor operator. Yet it is not always the operator’s fault. I make hundreds of the negatives I print, and if those negatives came direct from the dark-room to me, and I was in the habit of using a profane vocabulary, I am afraid I’d often be indulging in the pleasant occupation of cursing myself. Negatives as soon as they are ordered should be returned to the dark-room for careful examination, and a few minutes’ work with reducing agent or intensifier, local or general application, will save the printer hours of dodging, and attain a result which no amount of printing can reach. Careful dodging will also give the printing papers a fairer chance. Too many photographers expect the various developing papers to give wonderful results irrespective of the quality of the negative, entirely forgetting the fact that papers can only register what is in the negative.

While on the subject of the printing room I want to offer a few hints upon little necessary items which are incidental to printing. Let me here explain that these little ideas are not all original, some of them have been handed to me in the hope that they would be helpful, and I pass them along to you in the same spirit with the assurance that I have found all of them very useful.

For cleaning the back of a negative before printing, the sanitary and best way is to put a little pulverised pumice in a

piece of coarse-weave flannel cloth. A slight rubbing, without moisture, is sufficient to clean the negative, and, if the negative is very dirty, breathing upon it and then rubbing with the pumice pad will be found sufficient.

A good system of lighting a printing machine is to use twelve 60-watt lights for 11 x 14 size opening, instead of four higher power ones. Fig. 2 will show why. I have numbered each light to illustrate what I mean. Supposing your negative is not

Fig. 2.—Battery of twelve bulbs for an electric printing box.

evenly balanced, and the thin section of it lies over light No. 9, break the contact on that light by unscrewing the bulb, and you "even up" your print; or, *vice versa*, if you have a dense section just insert immediately under it a higher watt—say 75 nitrogen—and in most cases it brings the desired result. I have found this system very efficient in saving time with tissing,

Fig. 3.—Multiple-vignette print made at one printing from cut-up film negatives, etc. The reason for so many lights is to enable the printer to localise the corrections better.

Many studios make a speciality of combination prints, four or five on one sheet of paper. I have found by using Portrait Films for the negatives that they can be cut down, fastened to one piece of glass, vignettted, and printed under one exposure instead of having to vignette and print each negative separate, which is a tedious process at the best. Fig. 3 will explain this. This print was made under one exposure.

In making enlargements one sometimes runs across a negative that (especially when using the Cooper-Hewitt light) is too

dense to focus correctly. A simple method to overcome this difficulty (which probably most of you adopt) is to get the approximate focus, then insert a thinner negative, get the final focus, and replace the negative you wish to enlarge, and then expose.

Many a time a printer will pull the black envelope out of the outer covering of a dozen sheets of paper. There may be other black envelopes lying around, and confusion as to what grade of paper they contain will be the result. To avoid this purchase a white pencil and mark the grade on the black envelope as you open it: the pencil mark can easily be detected in the dimmest light.

Before proofing your negatives, number the glass side of them with a negative grease pencil. Then, if two negatives are very similar in position you will have no difficulty in telling which one the customer has chosen when the proofs are returned.

If one has to print an artist proof sheet from a subject that is not in the centre of the negative, one can get a little more latitude in width by moistening the finger with a little opaque and running it along the edge of the negative. This will enable one to print to the edge of the negative without getting a black line.

There are various methods of making a diffused print from a sharply focussed negative. I much prefer the result obtained by the following method. Roll your developing paper with the emulsion side in until it stays with a reasonable curve; place in position upon the negative, and hold firmly in contact with the tips of the fingers of one hand, as shown in Fig. 4. Now start the exposure, and with the other hand gently press paper in contact with the negative, allow it to recoil as soon as it

Fig. 4.—Making diffused print by giving some of the exposure with part of the paper out of contact with the negative.

touches, and repeat the operation for about one-half of the exposure; complete the rest of the exposure with the paper in absolute contact with negative. It sounds a bit complicated, but in practice is very simple, and gives a result that is very pleasing.

Absolutely the best method I have found for cleaning discarded negatives is to leave them overnight in used pyro-soda developer. In the morning you will find that a rinse in cold water is all that is necessary to give you the clearest and cleanest glass obtainable.

HERBERT G. STOKES.

(To be Continued.)

SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—The annual meeting of the association was held on Tuesday, September 23, in Stephenson's Café. A fair attendance of members has to be recorded, and an interesting evening was spent. The balance-sheet showed a credit balance of over £7 and the prospects of the association are very encouraging. An election of officers took place, with the result that all were re-elected as before. It was decided to invite manufacturers to give demonstration of their products during the coming session, and efforts are to be made to secure new members.

HAMMERSMITH, HAMPSHIRE HOUSE EXHIBITION.—The first of the short interval exhibitions is now open at Hampshire House, Hammersmith. It consists of the originals of "Photograms of the Year," which includes the cream of last year's Salon pictures. Though not attaining the standard of this year's Salon pictures—an exceptionally interesting and high one—they are well worthy of examination and detailed study. Their careful selection and cosmopolitan character are great advantages for purposes of comparison, for being all in the first flight one's judgment is not prejudiced nor attention diverted by the presence of any of a mediocre character.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).

Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).
 Miniatures (Sept. 19).
 Printing Portrait Negatives (Sept. 26).

WEDDING GROUPS.

As a rule wedding groups do not form a particularly remunerative class of work, and are moreover rather trying jobs, but as a rule they are approached with a certain amount of enthusiasm, not unmixed, on the part of the younger members of the profession, with a little anxiety. One thing that is to the good is that each job serves as an advertisement, as many of the copies come into the hands of those who are likely to want similar groups in a few months or perhaps a year or two. Wedding orders generally want a little looking for, and it is desirable to have a working agreement with those tradespeople who will have early news of the "happy event." Among these are florists, milliners, jobmasters, caterers, and the like. It is a curious thing that the group is often overlooked in the hurry of preparation, so that if the photographer does not approach the bride's friends in good time the opportunity may be lost. It is a good plan to submit three or four specimen groups in a portfolio with a polite note quoting prices.

The next thing to be done is to ascertain where the group can be most conveniently taken. If it can possibly be managed, this should be at the studio, as not only can the difficult contrasts of lighting be more satisfactorily handled, but the members are more easily handled than at home. As a rule the work is done at the bride's home or at the hall where the reception is held, and in this case it is desirable to get the time fixed as early as possible, as after refreshments have been freely partaken of it is sometimes difficult to avoid "moves," while the difficulties of posing and arrangement will be increased. Great tact is often called for when it is necessary to subdue the exuberance of the funny man without giving offence.

One must start with some general idea of arrangement of the figures, the great thing being to balance the light and dark clothing so that a spotty effect is avoided. By this I mean that it is not desirable to place a lady and gentleman alternately, but rather to group the light and dark clothing in masses. A very common scheme which is usually satisfactory is to have the bride and bridegroom seated in the centre; on either side of these are the parents or other close friends; behind this line are grouped the bridesmaids, and other figures are grouped at the sides of these two lines and on a third line behind, if necessary, care being taken that important personages are not relegated to the background. If young children are to be included, they may be placed in front, but not so as to hide any portion of the

bride's dress. These little ones may stand in the front row between the elder folk, if preferred.

The choice of a background for an outdoor group is often a difficult one. If it be possible to include the house it will usually improve the lighting and give interest to the picture. Foliage backgrounds are not so good, and should be avoided if possible. Above all, no heads should be allowed to stand out against the sky above foliage or fence. A very nice grouping of a more informal character can easily be arranged where steps coming down from a doorway or French window are available. In this case all the figures may be standing, but due care must be taken that the principal figures are in the most commanding position. Overcrowding on the one hand and straggleness on the other must be steered clear of.

It may be suggested, in extremely unfavourable weather, that flash-light may be used, the group being arranged indoors. Hence it is advisable always to be prepared with a flash-lamp and supply of powder. A friend of mine recently saved the situation in this way when a storm prevented outdoor work from being attempted.

As a general rule 12 x 10 is the size adopted for such groups; it should be pointed out that in smaller sizes the individual portraits are not large enough to be of any value. People expect to pay very much less for whole-plate than for 12 x 10, yet, except for cost of materials, the trouble and expense are the same in either case. If the group is to be an outdoor one, extremely rapid plates should not be used, for with a slower plate and fuller exposure more harmonious results can be obtained: 200 H. and D. is quite rapid enough. It is absolutely essential to the best results to use backed plates, and to ensure this on short notice it is wise to keep a tube or pot of backing always ready for use. There is no need to wait for it to dry if a piece of thin brown paper be placed at the back of the plate to keep the spring of the partition from touching the colour. A little methylated spirit may be used to thin the colour and will facilitate drying.

More wedding groups are spoiled by over-development than by any other cause, and it is as well to commence development with a solution half normal strength. This should with time give sufficient density in the black coats before the white dresses are overdone. In case there is too much contrast it should be reduced with persulphate in preference to ferri-

cyanide. Persulphate is not difficult to use if all traces of hypo are kept from the plates and a sufficiently strong solution, say 10 per cent., of sulphite of soda used to stop the action.

Printing and mounting are matters for individual tastes. Many photographers still print outdoor groups in P.O.P. and mount them upon plate-sunk mounts. I should prefer a fine platino-matt surface bromide mounted upon a stout cream "art surface" card with bevelled edge leaving a margin of about one inch. That is more convenient for posting than the old mount with a three or four inch margin.

Portraits of the bride and bridegroom only are usually more remunerative than the ordinary groups, and if possible should be taken in the studio. Often the arrangements for the journey prevent this, so that the pictures have to be made "at home," and it is hardly necessary to say that in most cases an indoor portrait will be preferred to an outdoor one. Most decent-class houses have a room with sufficiently large windows for this to be done.

The opportunity of suggesting miniatures in bridal dress should not be lost, as it is usually much easier to obtain orders at a time when the customers are pleased with themselves and everybody else than it will be later on when the bills begin to come in.

PRACTICUS.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, September 15 to 20:—

ROLL-FILM DEVELOPING.—No. 22,912. Devices for developing roll films. C. L. Bambrick.

PRINTING FRAMES.—No. 23,006. Photographic printing frames. J. P. Hansen.

STEREOSCOPIIC COLOUR PHOTOGRAPHY.—No. 23,075. Stereoscopic colour photography. R. Highet.

PRINTING MACHINES.—No. 22,765. Photographic printing machines. Kerotype, Ltd., and A. E. Thumwood.

PROJECTION.—No. 23,031. Optical lanterns, cinematographs, etc. W. Pemberton.

COLOUR PHOTOGRAPHY.—No. 22,884. Production of photographic films in natural colours. T. M. Sanders and R. Wellesley.

SELF-PORTRAITURE.—No. 22,858. Self-taking apparatus for cameras. A. Watt.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR PHOTOGRAPHY.—No. 119,854 (Oct. 9, 1917). The invention consists in a particular adaptation of copper toning a silver image for the purpose of making a two-colour or three-colour print or film. Details of the process appear on another page in the "Colour Photography" supplement. The following are the claims made in respect to the invention:—

1. A colour photograph or film, comprising colloid material containing different portions of the colloid, respectively a red copper-toned silver image and blue-to-green image blended with the red copper-toned silver image.

2. A colour photograph or film, comprising a colloid layer supported on a transparent carrier, and containing a red copper-toned silver image at either the interior or exterior surface of the said layer, and a blue-to-green image at correspondingly either the exterior or interior surface.

3. Method of producing a colour photograph or film from suitable colour selection negatives consisting in first printing a silver image by exposure from one side, and subsequently colour-toning such image, re-sensitising, and printing by exposure from the opposite side to produce a blended image of a different colour.

4. Method of producing a colour photograph or film from suitable colour selection negatives consisting in first printing a

silver image through the transparent base of a sensitised colloid layer, and subsequently colour-toning it, and printing by face exposure a second image of different colour in the same layer.

5. Method of producing a colour photograph or film from suitable colour selection negatives consisting in first printing a convertible silver image at one surface of a colloid layer by exposure through its carrier, and subsequently copper-toning this to a red colour, and after such silver-printing, iron sensitising the same colloid layer and printing a cyanotype image on the opposite face.

6. Method of producing a colour photograph or film from suitable colour selection negatives consisting in first printing a convertible silver image at the interior surface of a colloid layer by exposure through its carrier, then sensitising the exterior surface of the same colloid layer and printing thereat a colour image such as blue-to-green in register with the silver image, and thereafter colour-toning the silver image to a different colour. Mess-Ives Corporation, 1,201, Race Street, Philadelphia, assignees of Frederic Eugene Ives.

Liverpool Amateur Photographic Association. "Photography as Applied to Presswork." F. Curson.

CROYDON CAMERA CLUB.

MR. H. F. FARMER gave a practical demonstration on "Carbro Printing," a process bearing a strong family resemblance to Ozobrome, but having many features apart. Among other things, it is claimed for the newcomer that the uncertainty of Ozobrome has been entirely eliminated, and in addition, that the scale of the Carbro print may be altered with equal precision, in the direction of increased or decreased contrasts. Such claims appear to be fully justified by the highly interesting demonstration given. A member of the club, Mr. Jobling, carried through on his own one Carbro print, to a perfectly satisfactory conclusion.

A full description of the process is deferred, but it is only fair to pay a tribute to an enthusiastic amateur for the vast amount of patient experimental work which must have been undertaken before Carbro was placed on a practical basis, and all done for the pure love of the thing, and the advancement of photography. The unanimous opinion of the club was that it is a process likely to appeal very strongly to amateurs in general, and also, it may be added, likely to be of utility to professionals, but that the future alone can decide.

It should be understood that Mr. Farmer in no way belittled the Ozobrome process, indeed, quite the reverse, and the enumeration of the points of difference were only given as indicating the advance made. Mr. Stutchbury, Mr. Inskeep, and others who had worked the Ozobrome process narrated their experiences, and welcomed the new process with great cordiality. Mr. Harpur simply radiated enthusiasm and words which are never frozen or stereotyped. He pointed out that all the beauties of the carbon process were available provided one was provided with a good quality bromide print. Here he somewhat overstepped the mark, for Carbro obviously is limited in gradation to that afforded by bromide papers, which cannot pretend to possess the long scale characteristic of the Autotype or carbon process.

It transpired incidentally that Mr. Farmer, who has knocked about all over the world, invariably follows the doings of the merry Croydonians with interest, and when he came to England consulted some editorial beatitude as to appearing before them. Being informed that a revolver, metal helmet, and gas mask were usual

precautions, he adopted another precaution by dropping in one evening, without revealing his identity, to discover the lay of the land, and found the prospect congenial.

A most hearty vote of thanks was accorded to him with great resonance for an evening almost unique, containing as it did the elements of novelty, a *rara avis* in these days.

Commercial & Legal Intelligence.

AN ENLARGEMENT SWINDLE.—At the Penge Police Court last week, Charles Hawkins, of Brixton, was sentenced to nine months for obtaining by false pretences 7s. from Ernest Buller, of Upper Norwood; 5s. from Mrs. Martha Williams, of 1, Richardson's Place, Greenwich; and £1 from Mrs. Winifred Howard, 42, Lenthorp Road, East Greenwich. Accused was identified as the man who called on witnesses for orders to enlarge photographs. Most of the people from whom he obtained money were poor, and he had made a special feature of soliciting orders to make enlargements of soldiers' photographs. Prisoner pleaded guilty, and Detective-Sergeant Ottway said he had obtained orders under various names. He had apparently canvassed all over London, and occupied one room with his wife at Brixton, but there was no photographic apparatus there whatever.

LEGAL NOTICES.—Notice of intended dividend is given in the estate of Charles Frederick Siedle (trading under the style of Siedle Bros.), photographer, 60, Walter Road and 13, Heathfield Street, Swansea. Proofs must be lodged on or before October 8 with Henry Rees, Official Receiver, Government Buildings, St. Mary's Street, Swansea.

A first and final dividend of 1s. 5d. in the £ has been declared in the estate of Joseph Edmund Bramwell, photographer, 38, Beechville Avenue, and lately carrying on business at 124, Westborough, Scarborough. This dividend is payable at the Official Receiver's Office, 48, Westborough, Scarborough.

NEW COMPANIES.

SANDERSON, SUTER, AND CO., LTD.—This private company was registered on September 23 with a capital of £5,000 in £1 shares. Objects: To carry on the business of manufacturers, importers, and exporters of and dealers in nautical and scientific instruments and photographic apparatus, glass goods, etc. The subscribers (each with one share) are:—R. F. Sanderson, 3, Peter Street, Manchester, shipowner; A. E. Warburton, 8, Peter Street, Manchester, timber importer; W. G. Ineson, 8, Peter Street, Manchester, timber importer. The first directors are:—R. F. Sanderson (managing director), A. E. Warburton, and W. G. Ineson. Qualification £50. Registered offices: 8, Peter Street, Manchester.

WALTER COLLEY, LTD.—This private company was registered on September 10 with a capital of £2,000 in £1 shares. Objects: To carry on at Birmingham or elsewhere the business of photographic dealers, etc. The first directors are:—A. J. Colley, 81, Taylors Road, King's Heath, Birmingham, drug merchant; W. Holt, 73, Handsworth Road, Small Heath, Birmingham, chemist; Mrs. A. Colley, 81, Taylors Road, King's Heath, Birmingham; Mrs. S. M. Holt, 73 Wordsworth Road, Small Heath, Birmingham. Registered offices: 151-3, Shercoo Street, Birmingham.

SUB-MARINE PHOTOGRAPHY.—Details have been published of the method by which a remarkable photograph of the wrecked "Laurentic" was taken at the bottom of the Atlantic on the Donegal coast. The camera was enclosed in a water-tight iron tank, tested to stand pressure 20 fathoms deep in water, and fitted with a vessel's porthole glass. A diver then took it down, and electric bulbs were lowered from the Admiralty salvage steamship to provide light for the picture. After exposure of an hour and a-half, it was found that an admirable photograph of the wreck had been obtained.

WAR GRAVE PHOTOGRAPHS.—The Directorate of Graves Registration and Enquiries is unable to receive further applications for photographs of graves in the various theatres of war, but it is hoped that the requests already received will be completed before the close of the year. There is now no prohibition on the use of private cameras. Since the work was undertaken, 120,000 photographs taken in France and Belgium and 2,400 photographs taken in other theatres of war have been supplied to relatives. The requests that have still to be dealt with number 35,795.

HYPO-ALUM v. SULPHIDE TONING.

To the Editors.

Gentlemen,—“Thermit's” article on sepia toning (“B.J.,” September 25, 1919) interests me much, as on all hands I have heard of troubles in toning. Knowing that prints can be toned successfully, I have always been surprised that a better understanding of toning processes has not become general. For many years in Australia I have made sepia prints with regularity as to colour and freedom from many ills that so many run against—blisters, washiness, weight, and double toning. Also we have always been able to get at will any colour from the light-yellowish tone, so much disliked, to a deep chocolate.

We developed with ferrous oxalate, which was allowed to become old by use on bromides earlier in the day. The toning bath was hypo-alum. The bath in use was several years old and was added to as became necessary, no bath being added under the age of three days. The prints lose practically nothing in depth: the colour is regulated entirely by exposure.

Prints were given a very short washing after fixation and transferred direct to the toning bath. Late in the afternoon the bath was warmed for a few minutes and the prints left overnight to tone. In summer our dishes were stood on the asphalt roof yard, and with slight attention—the occasional turning of the prints—three batches daily were toned. After toning all prints were washed for two hours in running water, as were all prints in this establishment.

Blisters I have only seen on one grade of paper by one maker, and in consequence this was never used for sepias. The other grades of paper by this firm were quite satisfactory.

The sulphide process, owing to the numerous blisters, I have not used much. Many firms use it, and experience the usual irregularities of the process. In England my biggest trouble has been caused by the light affecting the prints after bleaching. Of late, in consequence, I have toned in the dark-room with the aid of electric light. I do not know of any paper normally free from blisters when toned by the sulphide process, our summer having to take some blame for this, though winter does not see us free from them.

Seeing that sulphide toning is looked on so unfavourably it is a great wonder that more men do not use hypo-alum. It requires a certain amount of work to get used to the method, but the regularity of result in every way should surely make this worth while. I have always found sepia work both pleasant and profitable, and this without any attendant anxiety.—I am, yours faithfully,

30, Shenley Road, London, S.E.5.

P. A. PEACHEY.

BRITISH LENS MAKERS.

To the Editors.

Gentlemen,—It is very satisfactory to read, in Messrs. Ross's letter to “The Times,” an extract from which you make on p. 569 of “The British Journal of Photography” for September 26, that “. . . we have undoubtedly not only caught up the German manufacturer, but have in many cases surpassed him.”

This being the case, I trust this standard will be kept up, so that the British made lens will occupy the position in the world it did in the old R.R. days. There is no question the British made pre-war lenses were, as a whole, inferior to the German, since the introduction of the anastigmat. Please note, I say, as a whole; selectively it was possible to find occasionally a British the equal of any German lens; for instance in 1898 I bought an anastigmat by a well-known English maker, which was as good in every way as any German lens I tried against it, but though I have examined many of the same series since, I have not yet found its equal amongst them. Now take a lens made by a German firm of the same standing, one could purchase a German lens of a given series at one time and place, and then another of the same series somewhere else at another time, and on examination would find the performances of the two lenses identical. I regret I have not found the same applies to the British lens. To give another example, quite recently I have,

examined two lenses by an English maker of similar series and equivalent focus, one proved to be a very fine lens, the other I would not use, even if paid for doing so.

My grounds for making such a sweeping condemnation is that photography has been my hobby for over 30 years. I am interested in the optics of it, and have owned probably as many lenses (British, French, German, and American) as any amateur; all these lenses have been critically examined by me according to the accepted methods of Traill Taylor, Beek, and others, and also by use in the field. Please note I have no kindly feeling to the Germans, nor over have had since my school days, but in scientific matters one must be honest; further, my remarks do not apply to British lenses before 1896, nor to post-war lenses, nor to portrait lenses, here, as far my tests go, the British made have always been ahead.

This letter is already longer than I intended, but I would suggest to British lens manufacturers, when issuing reproductions of prints produced by their lenses, as advertisements, that some particulars, such as aperture, and equivalent focus of lens, size of plate, and date be appended. The reproductions I have seen in the photographic press bear no evidence that they were difficult subjects for anastigmat lenses, in fact I could produce as equally good results of most with an R.R. lens I have had for 30 years.—Yours faithfully,

A. R. F. EVERSHERD.

Highgate, N.6., September 30, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. G.—Yes, a licence is required to open a branch establishment. If your branch studio is to be opened in a town in Lancashire, the licence office to which application should be made is at the New Arts Buildings, Liverpool.

C. T.—Yes, a licence is necessary. The address of the office to which to apply is Fine Arts Building, Liverpool. You can get a copy of the Licensing Order by sending a penny stamp and a stamped address envelope to H.M. Stationery Office, Kingsway, London, W.C.2.

R. B.—As a rule, with most papers, sodium sulphide yields a better colour than ammonium sulphide, but any paper which will tone at all by the sulphide process will yield a quite agreeable colour with both. As regards permanency, there is no difference between the two.

N. D.—For a studio of your size the focal lengths of the two lenses are the best you can have for the purpose, since they are the longest foci which can be used in the space. With four 1,000-c.p. half-watt lamps you ought to be able to get short exposures at the full aperture of the lenses and even when stopped down to f/6.

B. W.—We are very sorry that we do not know of any formula having been published for the making of gelatine ferrotype dry-plates or postcards. This is a branch of manufacture which attracted scarcely any of the experimentalists in the early days of the dry-plate process, so that, so far as we know, there is no literature on the subject.

M. N.—The only book in print giving instruction in collotype is Wilkinson's "Photo-Mechanical Processes," published by Messrs. Hamptons, Cursitor Street, E.C., price 4s. A text-book alone is not sufficient for learning collotype; it should be supplemented by practical instruction, the nearest place (to you) for which is the Manchester College of Technology.

P. H.—1. As you find exposures still so long it would be worth your while seeing if you can get one of the high-power focus type half-watt lamps from the General Electric Company, Ltd., 67, Queen Victoria Street, London, E.C. If you can, and use it with a condenser in your enlarger, it would certainly solve the problem of your long exposures. This type of lamp has been unobtainable for a good many months, but probably can now be had again. 2. The vanadium formula gives a colour very similar to your specimen, but it is a very troublesome formula to make up, and we think you could get a good enough match with the green toning preparations obtainable from the Leto Photo Materials Company, Roman Wall House, 1, Crutched Friars, E.C.

B. A.—We have no information as to the workability of the true-to-scale formula recently contained in a patent specification. A formula for the true-to-scale composition, which was given some years ago by Mr. R. B. Fishenden, of the Manchester Process School, is as follows:—

Glue	8 oz.
Water	to make 16 oz.
Add—	
Gelatine (dissolved in water to make 2 oz.)...	1 oz.
Ferrous sulphate	½ oz.
Glycerine	½ oz.

A second formula is:—

Gelatine (Coignet's)	1 lb.
Water	4½ pints
Size powder	1 lb.
Iron alum (ferric ammonium sulphate)	1½ oz.
Water	1 pint

Dissolve the gelatine in the water, then add the size powder. Dissolve the alum in the water, then add to the glue solution gradually stirring all the time.

SWADLINCOTE PHOTOGRAPHIC SOCIETY.—Efforts are now being made to re-form the Swadlincote Photographic Society, which has been dormant during the war. At a meeting held at the Swadlincote Town Hall, when Mr. A. Gretton presided, Mr. Donald Lee was elected secretary pro tem.

SUMMARY.

The 1920 British Journal Almanac, now in preparation, will be published early next year in its pre-war edition of 25,000 copies.

In a contributed article Mr. H. F. Farmer gives full working details of the modification of the Ozobrome process which he has named Carbro. The tissue is "sensitised" in a single bath, ordinary carbon tissue is used in making the carbon prints, and the process possesses the special feature of allowing of greater or less contrast being produced in the prints by a very simple modification of the working. Mr. Farmer also describes a very simple and efficient form of squeegee board, and has worked out a table of times for the immersion of tissues of different colours in the sensitising bath. (P. 583.)

In the further instalment of the paper by Mr. Herbert G. Stokes the construction of a rotating trimming desk is described, as also an efficient form of retouching bench for use both by day and artificial light. (P. 588.)

In his article this week "Practicus" deals with the simple forms of combination printing which a photographer now and again is called upon to carry out. He particularly describes methods suited respectively to print-out and development papers. (P. 587.)

In a letter to the Editors a correspondent describes at length the card-index system employed by himself for keeping track of orders passing through his studio establishment. (P. 594.)

A contributor to "Assistants' Notes" deals with the system which can be followed in carrying out a course of self training in learning to draw. (P. 590.)

Caution as to the storage of sensitive papers is contained in an extract from Rajar "Trade Notes." (P. 590.)

In a leading article we seek to show the useful information which can be obtained in diagnosing the cause of white spots on negatives from the use of a magnifier. (P. 582.)

A new construction of large-aperture telephoto lens is among the Patents of the Week. (P. 591.)

Working formulae for the sensitising of canvases are given by a correspondent. (P. 594.)

Firelight portraits will shortly be a reasonable type of photographs for window specimens. (P. 582.)

In preparing photographs for use as Christmas gifts photographers might give attention to a somewhat more decorative scheme of mounting. (P. 581.)

In meeting the competition of the camera pressman in the photography of wedding groups, the portrait photographer, in addition to exploiting his greater opportunities, may often require to meet the pressman on the latter's own ground. (P. 582.)

EX-CATHEDRA.

The 1920 Almanac. The fifty-ninth annual issue of the "British Journal Almanac" is now in active preparation. On the assumption that industrial conditions continue fairly normal, it will be published during the first week of February next. Assuming, also, that no untoward events interfere with our plans, features of the book which during the last two or three years had to be withdrawn in consequence of paper rationing will be replaced, and the edition of the volume will be restored to its pre-war figure of 25,000 copies. On behalf of our publishers it must be said that the compulsory cutting down of supplies of the book to dealers and exporters in this country as well as to agents overseas was a policy which they were compelled to adopt with very great regret. It is hoped, however, that the demands for this issue, which may be said to be the first to appear after the conclusion of the war—the 1919 volume was produced for the most part during the period of hostilities—will be reasonably met. In consequence of the railway strike the time for the preparation of the forthcoming issue has been curtailed by a week, so that intending advertisers will very greatly facilitate the work of our publishers by giving the earliest possible intimation of their requirements. The necessity for this request could hardly have been foreseen when preparing the circular announcing the Almanac, which now should be in the hands of every firm in the trade, but we hope that advertisers will make a note of this intimation and, wherever possible, act upon it.

* * *

Gift Portraits. Photographers have not failed as Christmas approaches to point out the desirability of making the seasonable gift take the form of a portrait, but not all of them have realised the necessity for clothing the print in an attractive manner. Many do not make any attempt to present any other styles than those they use all the year round, and these are often a little too plain for the particular purpose. When we note the taste and care with which jewellery, draper's goods, and even chocolates are packed, a photograph stuck upon a piece of brown paper has anything but a festive appearance, and we think that in many cases increased business would result from the introduction of more elaborate styles of entourage. We believe the public would welcome a smaller picture in a very good quality of folder in place of a large print plainly mounted at the same price. Large prints call for very careful and substantial packing, and even then are liable to damage in transit. Another direction in which business might be extended is that of coloured work. There are now many well-trained colourists available, so that it should not be difficult with a good-class clientèle to sell coloured prints by the dozen instead of by the unit as we do now.

Seasonable Specimens.

The approach of winter gives the opportunity for the display of a few specimens of a style which is not often in evidence nowadays. We refer to the firelight effects which some photographers have produced very successfully, although others have been deterred by the fear that elaborate arrangements were necessary for lighting. This may be true if daylight only is available, but with artificial light there is no difficulty, as the light can easily be transferred to any desired position so as to give the effect of the glow from an ordinary fireplace. To our mind this style is most effective on whole-plate or larger sizes, and as cold tones are desirable enlargements may be made upon a "carbon" or velvet surfaced bromide paper, which, when dyed, gives an excellent result. One thing to be avoided is a pinkish tint in the dye used, as this quite spoils the firelight effect. A deep orange is perhaps the best colour, and sometimes this is improved by a dip in a weak solution of ordinary red ink. Such pictures are best framed close up in dark oak, but in any case a light mount should be avoided.

* * *

Labour Celebrities.

The recent prominence into which the "Eleven" and afterwards the "Fourteen" of the trades union world have come as a result of the negotiations over the railway strike prompts the observation that for men of their position in the industrial life of the country there is a conspicuous absence of their portraits in the bookstall and shop displays of postcards throughout the country. Apparently, even within the circle of their own unions, portraits of labour leaders are not good sellers. The recent newspaper publicity accorded to them, and particularly in the illustrated Press, may perhaps bring about a change in this direction, so that we may have Mr. Gosling and Mr. Robert Smillie rubbing shoulders with Gerald Du Maurier and the universal Gladys Cooper in the postcard shops. On the other hand, it may reasonably be thought that at the present time the attractiveness of the trade union organisers, even to those who benefit by their labours, is expressed in terms of satisfaction with increase in wages rather than in any idolisation of the individuals. We shall see what we shall see, but for the present it seems pretty safe to say that a postcard publisher making a specialty of a series of portraits of trades union leaders will, to put it mildly, be regarded as highly optimistic by his competitors.

* * *

Press and Portrait Photographers.

The question of a Press photographer poaching upon the preserves which the purely portrait photographer has come to regard as his own was discussed a little while ago, and was freshly brought to our notice during the past week at a wedding function. On the arrival of the bride at her mother's house after the ceremony a portrait photographer who had been asked to come and take some groups of the wedding party attended for that purpose. He was three-quarters of an hour late in keeping the appointment, but nevertheless spent something like an hour in making about half a dozen exposures on groups of the bride and bridegroom and of these latter with others of the party. He had scarcely packed up his apparatus and taken his departure when a motor-cyclist arrived with excellent finished bromide prints of the bride and bridegroom and the bridesmaids, taken as they were leaving the church. A Press agency's photographer had asked these members of the party to halt for an instant on their way to their carriages and had made several photographs, which were very good of their kind, and, at any rate, were thought to be excellent by members of the party, who evidently,

though perhaps unconsciously, found some added merit in them in the fact of their very rapid production. In large towns competition of this kind is bound to go on, and it is for the portrait photographer to consider how he shall deal with it. Plainly it is within his powers to offer the same kind of service as the Press agency, which, as a rule, will score over the carefully posed group in the more pleasing expression of the subjects, even though the photographs may be inferior technically. On the other hand, such photographs as can be made whilst the wedding party is dispersing from the church are usually not all which are required. Convention in most cases demands a group in which the parents and other friends of bride and bridegroom are included with them and are arranged with regard to the family connections. This is one way by which the business may be prevented from passing into the hands of the Press photographer, but obviously if the latter's competition is to be met it must be met on his own ground.

SOME FURTHER NOTES ON TRACING DEFECTS IN NEGATIVES.

A FEW weeks ago, in our issue of September 5, we had something to say on the lines of inquiry along which a photographer, who cannot call to his personal aid some expert advice, must work and think in solving his own difficulties. In those notes we selected, by way of example, the various causes, before and after exposure, which may lead to fogged negatives. Negatives which are defective in this respect are among those which are most commonly sent to us for our advice in helping the querist to identify the cause of his trouble, but as everybody knows they by no means exhaust the possibilities of going wrong which apparently, to many of the inexperienced, present themselves under a formidable aspect. In the case of other defects, it is often possible by more direct means to come to a conclusion as to what is the cause and what means require to be taken for prevention. For example, the occurrence of clear spots on negatives is a thing which a little commonsense inquiry will speedily trace to its source, yet it is a common experience of ours that many a tyro in the handling of plates will send such spotted negatives to the editor of a paper or some other adviser rather than take the trouble to think for himself and use his own judgment. It does not seem to occur to many that one of the first things which should be done in the case of such spotted negatives is to examine the spots under a fairly strong magnifying glass. For this purpose the ordinary focussing magnifier, particularly if of fairly decent power, is quite suitable. Another very convenient pocket instrument is the so-called folding linen-tester, much in favour among makers of half-tone negatives for examining the dot formation. One advantage of it is that its skeleton construction allows of it being used just as well for paper prints or for any opaque surface as for things like negatives which, with the ordinary focussing magnifier, can be examined by transmitted light. Another little piece of apparatus, also suitable both for negatives and prints, but less handy for the pocket than the linen tester, is the solid glass magnifier sold by dealers in postage stamps for examination of the details of stamps.

Incidentally, a magnifier of this kind is a very useful thing to have as a means of quickly distinguishing between different kinds of photo-mechanical prints. With a little practice it is easy to recognise in a moment the characteristic grain of lithographic and colotype prints, whilst, of course, the dot structure of fine half-tones is instantly disclosed. We mention this, as an aside, because we are not infrequently asked to say what photographic process has

been used for the making of prints, samples of which are sent. More often than not it turns out that such prints are not photographs at all, but are usually either collotype or photo-lithographs.

Now under a magnifier white spots which to the eye may appear just like any others will be seen to exhibit characteristic differences according to the circumstances which have caused them. If they are seen to have graduated or vignetted edges it can be pretty well taken for granted that the spots are due to air-bells adhering to the plate during development. A spot due to this cause is usually also quite circular in shape and of some size, say, from one sixteenth to one-eighth of an inch in diameter. Both the roundness and the vignetting of the edges mark the cause we have mentioned. The softening of the outline is no doubt due to the gradual dispersing of the minute bubble of air as development proceeds, this process, in turn, no doubt, being due to the air gradually dissolving in the developer. Thus developer gains access to the outside portions of the spot, although, as a rule, not to such an extent as to give any deposit of density upon the central portion. Inasmuch as these air-bells adhere with some tenacity to the gelatine film it will not do to suppose that simple rocking of the developing dish will detach them. Where conditions are favourable to their formation on the film, as, for example, by using aerated water from the tap for mixing the working developer, it is necessary that the whole surface of the plate should be swabbed over firmly with a tuft of cotton-wool as soon as the developer has been applied. On the other hand, there are much smaller spots, also clear, which, under a magnifier, are seen to be all kinds of shapes and also to be quite sharp in outline. These, in nine cases out of ten, are due to dust on the plate at the time of exposure. The preventive in this case is, perhaps, not that which will naturally occur to every beginner. It has so often been repeated in text-books that plates should be carefully dusted before being placed in the holders that the isolated worker, whose only guide is often the text-book, concludes that he has only got to dust plates with a camel-hair brush in order to be free from these defects in his negatives. Experience, in time, will teach him that the advice proves fallacious in practice. At the present time plates as taken from the makers' wrappings are free from dust to a remarkably high degree—the dust which accumulates on them before exposure comes almost invariably from the plate-holders themselves or from the dusty condition of the inside of the camera. Those who have cause to complain of negatives which are faulty in this way should try the effect simply of giving the plates a smart tap on the dark-room bench as each is put into the holder, and for the rest, take care that the plate-holders and the inside of

the camera are regularly wiped out with a slightly damp cloth. If this is done, it will be found that there is nothing to complain of as regards these defects on the negatives.

There are also to be met with, though very infrequently, clear spots of circular shape and sharp outline which often are considerably larger than those commonly due to air-bells. They may, however, be of almost any size, and if probed with a fine needle will at once disclose their cause by the absence of any emulsion coating. Spots of this kind, as we have just said, are most infrequent in plates by any maker of recognised reputation. Except for a very few rare examples, we can only recall having met them on plates which have been put upon the market by beginners in the emulsion-coating of glass, or, perhaps, have been bought at a job rate from another maker and offered at a price which necessarily implied that something was the matter with them. We can recollect having examined box after box of plates which were issued at a very "cut" price: without exception every plate was defaced, often to an extent which rendered it quite unusable, by spots of this kind. On the other hand, the maker of reputation cannot escape the charge of faulty manufacture if spots of this kind are brought to his notice, and, so far as our experience has gone, is never averse from accepting such responsibility readily, inasmuch as the bringing of it to his notice demonstrates the necessity of improving the work of the employees who examine plates before packing.

Sometimes the unsuspected clue to the cause of markings on a negative will lie very near to hand. We recollect an instance in which a well-known firm of commercial photographers was plagued by mysterious dark, circular spots about one quarter of an inch in diameter, which in a most erratic manner made their appearance on negatives, yet always at such definite distances apart that the cause was sought, fruitlessly as it turned out, in some defect of the lens. Trials with all kinds of lenses failing to eliminate the defect, it was suddenly realised that the positions of the spots corresponded roughly with those of the finger tips of the outstretched hand. That gave the clue: it was speedily discovered that in handling a number of plates before development, they were stacked on their edges in the dark-room, the glass surface of one in contact with the emulsion film of the next. The spots arose from the transference to the back of a plate of the impression of the finger tips (applied in pushing the plate into place) to the emulsion film of the plate next laid in position. A simple enough explanation, once the photographer had made the observation that the positions of the spots corresponded with those of the extended finger tips.

THE CARBRO PRINTING PROCESS.

[The following article embodies the work of several years' experiment, which its author, Mr. H. F. Farmer, has carried out solely in the aim of bringing to a state of working perfection the process of making carbon prints by contact, in presence of a "sensitising" solution from bromides. Mr. Farmer informs us that the name "Carbro" has been selected as distinctive in itself and as indicating the nature of the process, viz., carbon prints from bromides.—Eds. "B.J."]

THE process of making carbon prints from bromides is not new, as it was invented fourteen years ago by Mr. Thomas Manly, and has been familiar as the Ozobrome process. The Carbro process, which is now described, as will be observed, follows on the general lines of Ozobrome, but differs from it in the fact of the tissue being prepared by treatment in one single bath; also ordinary carbon tissue is employed in the Carbro process, in which it has been possible to standardise the times of treatment for tissues of different colour. Since

the publication of an earlier article outlining the Carbro process, the writer has received so much encouragement from those who have given Carbro a trial that it was decided to continue experimenting in the hope of making the working so mechanical as to bring it within the reach of the most inexperienced worker. This has now been accomplished, and altogether seventeen colours of Autotype carbon tissue have been successfully adapted to the process.

Early experiments soon showed quite a variation in the time

of immersion required for different colours, with dark blue at the short end (only $3\frac{1}{2}$ minutes), ranging to engraving black, with a lengthy immersion of ten minutes before detail was obtained in the high lights. It was found possible to work the whole of the thirty colours manufactured by the Autotype Co. in a single working bath, but the time of immersion of some of the colours was so unduly prolonged (as in the case of engraving black) that a second working bath was introduced for the purpose of reducing the time to something more convenient. With these two working baths the whole of the colours appeared to drop into two series, and the table given is probably the most convenient method that it will be possible to introduce.

A comparison between the two working baths will show that while the proportion of "B" and "C" differ, the quantities of "A" solution and water remain constant. This last point is most important, and the worker is advised to adhere to the figures as closely as possible, obtaining control for pictorial results by varying the proportions of "B" and "C" solutions only.

Temperature, too, has a considerable influence on the chemicals used, and the ideal temperature for the working baths is between 55° and 65° . It may be pointed out here that 55° to 65° F. is the normal temperature of a living-room in England both winter and summer, and as the process requires no dark room the whole of the work may be carried out in cold weather beside the kitchen fire.

The keeping qualities of the stock solutions are excellent, and the working bath, until used, and thereby contaminated with organic matter from the carbon tissue, keeps for months. This is a useful point, as it permits the mixing of the working bath a day or two before required, and, by keeping it in a living-room, the mixed solution will take the temperature of that room and be ready for use at any time.

For the information of those who are unacquainted with the Carbro process, the first part of this article gives full working instructions, while the latter part will contain information which may prove useful should any difficulties arise.

Briefly, a piece of commercial carbon tissue is "sensitised," and while wet brought into contact with a bromide print—this bromide acting as a "negative." These are allowed to remain in contact for about fifteen minutes, then separated, and the carbon tissue squeegeed to a piece of transfer paper. On this transfer paper the picture is developed, and the final result is a carbon print from the bromide. The picture is not, as in the single transfer of the carbon process, reversed from right to left.

The following are the stock articles required:—

- A good bromide print.
- Carbon tissue.
- Single transfer paper.
- Squeegee.
- Squeegee board.
- Dishes.

A flat squeegee is best, and a useful length for all prints up to 12 by 15 ins. is 8 ins. The dishes should be porcelain or enamel; papier-mache is too difficult to clean, and thorough cleanliness is essential. The drawing shows an easily made squeegee board which entirely prevents slipping.

It will be seen from the above that there is no great outlay for the initial work, and neither will the future require any additional expense.

The sensitising baths are made up from the following stock solutions:—

A. Bichromate of potash.....	45 gms.	400 grs.
Bromide of potash	20 gms.	175 grs.
Ferricyanide of potash.....	20 gms.	175 grs.
Water	1,000 c.c.s.	20 ozs.

B. Chrome alum.....	35 gms.	300 grs.
Bisulphate of potash	5 gms.	45 grs.
Water	1,000 c.c.s.	20 ozs.
C. Bisulphate of potash	5 gms.	45 grs.
Water	1,000 c.c.s.	20 ozs.

All the above appear to keep well if stored in a cool, dark place. From the stock solutions make up the following sensitising bath:—

Sol. A.....	50 c.c.s.	1 $\frac{1}{2}$ ozs.
Sol. B	9 c.c.s.	2 $\frac{1}{2}$ drams
Sol. C.....	6 c.c.s.	100 minims
Water	200 c.c.s.	7 ozs.

For convenience, this may be called *aa* bath.

This is a most useful quantity for half-plate; for whole-plate use 50 per cent. more, keeping the same proportions all through, and for 10 by 12 double the quantities.

First place the bromide print in cold water and allow it to become thoroughly soaked; now take a piece of carbon tissue, cut about half an inch larger than the bromide from which the Carbro is to be made, and immerse face downwards for a definite time, according to time and colour table *aa* given at the end of this article. About a minute before the end of the time of immersion of the tissue remove the bromide print from the water and lay it face upwards on the squeegee board. At the expiration of the exact time, withdraw the carbon tissue from the sensitising bath, and, after allowing it to drain for a moment, lay it face downwards on the bromide and squeegee into contact. Now mop off any superfluous moisture from the back of the tissue and cover with a piece of paper, or preferably waterproof cloth. Place a book over this to prevent the tissue from curling, and thereby losing contact, and leave them in this position for from twelve to twenty minutes—the exact time is not a material point if kept within those limits.

A detail which requires emphasis is that from the moment of contact of tissue and bromide the sensitising action begins; it therefore follows that once the two have touched there must be no attempt to adjust the carbon tissue if it has been laid down at the wrong angle, as such a course would inevitably result in a blurred or double image. Should any slipping occur, it is far better to squeegee and make the most of the resulting picture, as under no circumstance may the tissue be moved.

Towards the end of the time of contact of bromide and tissue (twelve to twenty minutes) take a piece of transfer paper cut slightly larger than the carbon tissue, and soak this in cold water for about half a minute if of the thin variety, and about a minute for the thicker papers. Complete wetting is necessary, but over-soaking has a tendency to lead to frilling and other troubles during development.

After wetting the piece of transfer paper, hold it up to drain for a moment, then lay it face upwards on the squeegee board. Now take the carbon tissue and bromide, still in contact, and by raising one corner of the tissue steadily pull the two apart; leave the bromide for the present, place the carbon tissue face downwards on the transfer paper, and squeegee the two into contact. Remove them from the board, place them between blotting paper with a book over them to prevent curling, and allow to remain there from twenty minutes to one hour (a couple of hours will do no harm). Go back to the bromide print, now bleached to a pale yellow, and place this in a dish of cold water for washing and redevelopment.

It is advisable to change the wash water during the first few minutes of washing, as the greater part of the sensitising bath, transferred from the carbon tissue to the bromide, washes out very quickly. Obviously, this water soon becomes a solution sufficiently strong to have some material effect on the bromide print. After changing the water the print may be ignored until the process is finished.

The development of a Carbro print is a far simpler matter than the development of bromides, no chemicals being required.

After sufficient time has been allowed for the pigment of the tissue to adhere to the transfer paper, tissue and transfer paper are placed in a dish of warm water. Start with a temperature of about 95° F., the hand being sufficient guide. Keep the two papers, still adhering, well covered by the warm water, and wait until the pigment commences to ooze round the edges of the carbon tissue. This usually takes a minute or two, and if at the end of that time the oozing is not very apparent, a little more hot water may be added, great care being taken that the temperature is evenly distributed. As soon as the oozing shows all around the edges, carefully lift one corner of the carbon tissue, and, keeping the transfer paper as much as possible under water, steadily strip the two apart. The transfer paper will now be seen to be covered with a thick coat of pigment, a smaller quantity remaining on the carbon backing. This piece of backing has now completed its work and may be thrown away.

Turn the transfer face downwards in the water and proceed with the development by holding one edge and gently moving the print over the surface of the water, great care being taken not to touch the bottom of the dish. A better plan, if the dish is large enough, is to gently splash the face of the pigmented transfer paper, and as the picture begins to reveal itself the splashing may be local for reducing any particularly dense part at the desire of the worker.

Development is complete when it becomes obvious that no more pigment will wash away, and the picture is laid face downwards in cold water to clear it from any loose pigment on its surface.

It will now be noticed that where the carbon tissue has been in contact with the transfer paper the latter is marked with a bichromate stain, to remove which the print is placed in a bath consisting of a 3 per cent. solution of alum, and allowed to remain until the stain has disappeared. This may be done immediately following development, or the print may be dried and alumined the following day. The alum bath may be used repeatedly until its failure to remove the stain shows that it is exhausted. Should the solution become very dirty it merely requires straining through a piece of old cotton or muslin.

This completes the process, and the bromide, after well washing (twenty minutes in several changes is all that is needed), may now be redeveloped, well washed, and is ready for further Carbro prints, no fixing being required.

It is most important that the redevelopment of the bromide print be very thorough, and the prints are best left face downwards in the developer for at least fifteen minutes. If this redevelopment is not complete it will be found that all succeeding Carbros will lack detail in the high lights, and once the high lights have suffered from this insufficient redevelopment there appears to be no means of retaining them in Carbro, except by slightly increasing the proportion of B solution in the sensitising bath.

Both for the original development of the bromide and also for redevelopment, M.Q., Azol, and amidol all give excellent results, the writer's preference being for the last mentioned. For redevelopment (which, by the way, requires no dark room and no fixing) it is better to omit bromide of potash from the developer.

Some Useful Notes.

In making first attempts with the Carbro process the worker is advised to try a preliminary test, using 3 cc.s (100 minims) less of C solution than the given formula, and, with two similar small bromide prints, give one piece of tissue an immersion of fifteen seconds less, and one an immersion of fifteen seconds more than the time given for the colour which is being worked. The transfer paper may be marked on the back for future reference, with the formula used and the time of immersion (example: A.50, B.9, C.3—4½ min.). This would form a per-

manent guide for future reference, and give the worker a clear idea of the effect of varying the time.

It is interesting to note here that the time of immersion may be well compared with the time of exposure of a bromide print—under-immersion (exposure) gives increased contrast, over-immersion (exposure) gives general flatness with high lights veiled. Over-immersion may be remedied by using hotter water for development; under-immersion has no remedy. If in doubt give the tissue fifteen seconds more immersion than the standard time.

Excess of B solution produces a general clogging, with a heavy deposit of pigment; excess of C solution slows the action of the bath, and longer immersion is needed to obtain definition in the high lights. At the same time it holds back the shadows and general flatness results. This last detail is very useful for a harsh bromide, as by the addition of about 3 cc.s (100 minims) of C, any degree of softness may be obtained, but don't forget to prolong the immersion from half to one minute.

The treatment of the original bromide print is an important factor in the final results obtained, and correct exposure and development are very essential. Over-exposure and under-development of the original bromide print produce great flatness, and the richness of the shadows is entirely lost in the final Carbro print. A weak bromide gives a weak Carbro, and for a weak negative the enlargement is best made on gaslight paper.

There are occasions when slight over-exposure of the bromide may be turned to useful account, as in the case of bald-headed skies. Slight over-exposure in bromide gives the appearance of fogging, but the deposit of pigment in the sky of a Carbro print gives a suggestion of colour. Wherever there is reduced silver in the bromide there should be a deposit of pigment in the Carbro print.

The figures of the time and colour table have been worked out for all the principal British makes of bromide papers, platino matt being the most useful. Some makes which appeared to contain very little silver required quite a lengthy immersion, one paper taking eight and a-half minutes for sepia. There is no doubt that any paper will give a good Carbro, but such a prolonged immersion as 8½ minutes might be very baffling for a beginner.

Some bromide prints (make forgotten, but either Paget or Wellington and Ward) made over eight years ago gave excellent results.

Gaslight papers, on the other hand, need only three-quarters of the time given for bromides (same proportion for all colours), and the exact proportion of Wellington and Ward gaslight to their bromide platino matt is 11/16th. Gaslight paper gives Carbro prints fully equal to those obtained by bromide, and is therefore a valuable asset when dealing with a flat negative.

Although the tables are given as working at a temperature between 55° and 65° F., it is advisable to keep as near to 60° F. as possible. Successful work has been done at 78° F., but above 70° F. trouble develops on account of the softening of the tissue necessitating great care to prevent slipping when squeegeeing to the bromide. Also there is danger of crushing the high-lights when squeegeeing to the transfer paper. Below 55° F. the activity of the chemicals varies in different proportions, upsetting the balance of the working bath. Obviously, too low a temperature is best avoided; it is an easy matter to raise the temperature by putting the bottle of working bath in warm water before pouring into the dish.

A convenient method of working a number of Carbro prints is to take them in lots of four. Put in the first tissue, then immerse the other three at regular intervals of two and a-half minutes, and by the time the last one is out the first will be ready for the transfer paper. Quarter-plate prints may be worked, if all of the same colour, with four prints on one piece of tissue. Lay them in a square on the squeegee board, with a

space of about $\frac{1}{4}$ of an inch between them, and cut the carbon tissue about $7\frac{1}{2}$ by $9\frac{1}{2}$; this gives a comfortable margin for squeegeeing. For all work it is best to cut the tissue about $\frac{3}{8}$ of an inch larger than the bromide to allow for error when placing the two in contact.

For economy and convenience in working an excellent plan is to classify the bromide prints according to the desired colour, then, having mixed one working bath, continue with the colours belonging to that bath until the mixed solution is exhausted. It is worth noting that filtering after use will increase the keeping qualities of the working bath, but the bath is very cheap and there is no need to use stale solutions.

Carbro has many advantages over bromide printing:—It is permanent pigment; and you know before you commence working what the final colour will be. This cannot be said of bromide toning. It is simpler than bromide making, and you have a choice of seventeen colours, with about ten different surfaces of paper support. In cost, Carbro has a fractional advantage.

Beware of air bubbles on the tissue during immersion. This is best avoided by lightly pressing the paper to the bottom of the dish and stroking the back of the tissue during the first minute of immersion.

Accurate measurement of all solutions is imperative. One c.c. (15 minims) more or less of B or C solution might make a difference of half a minute in the sensitising bath.

Store all solutions in the dark—light has a very powerful action on bichromate, and also on ferricyanide. In the dark these two are fairly stable.

Should the working bath suddenly give a very harsh print it is an indication that it is exhausted.

Oxalic acid may be substituted for bisulphate of potash, but its keeping qualities are not good, especially in the mixed bath, and its use is not recommended. Bisulphate of potash can be obtained from Messrs. Johnson and Sons, Cross Street, Finsbury, London, and must not be confused with the bisulphite salt.

The process is suitable for transparencies, and prints on wood and silk, the method of preparing the support being the same as that given for the carbon process in the Autotype Co.'s booklet. For transparencies, give a rather longer immersion than for paper support, half a minute being sufficient for most of the colours.

And just one "don't"—don't attempt modification of the working bath until you have become acquainted with the process. If you have any difficulty write to the Editor of the "B. J." and ask him to pass the letter on.

Squeegee Board.

The accompanying sketch shows a very useful type of squeegee board, designed to prevent slipping. It is inexpensive and easily made. The strips along the bottom should be about half or three-quarters of an inch in thickness, so that the fingers may be inserted under the board, while the thumb presses the hinged piece on the top. A pencil line should be marked the full length of the board, as a guide for laying down the bromide print; and three-eighths of an inch further back, another line as a guide for the tissue. The rubber strip runs the whole length of the hinged piece, and the best thing for the purpose is a piece of studded rubber, rather thin, such as is used for office stair matting. Failing that, a piece of square elastic about an

eighth of an inch thick. The rubber can be fastened on with very small headed nails or tacks placed fairly close together.

The upper illustration shows the hinging of the clamping strip at the requisite height above the base. In the lower drawing is indicated the edging of studded rubber.

Time and Colour Tables.

The table for use, at a temperature of 55° to 65° F., and for working bath (aa), is:—A, 50; B, 9; C, 6. Water, 200 c.c.s., i.e., A, $1\frac{3}{4}$ ozs.; B, $2\frac{1}{2}$ drachms; C, 100 minims. Water, 7 ozs.

Colour of Carbon Tissue.	Time of Immersion in Sensitising Bath.
Dark Blue	$3\frac{1}{4}$ minutes.
Terra Cotta	$3\frac{1}{2}$ "
Standard Brown	$4\frac{1}{4}$ "
Sepia	$5\frac{1}{2}$ "
Sea Green	$3\frac{1}{4}$ "
Vandyck Brown	$5\frac{1}{2}$ "
Bottle Green	4 "
Italian Green	$4\frac{1}{4}$ "

For contrast, omit "C" and shorten time by $\frac{1}{2}$ minute.

For working bath (bb):—A, 50; B, 16; C, 16. Water, 200 c.c.s., i.e., A, $1\frac{3}{4}$ ozs.; B, 5 drachms; C, 5 drachms. Water, 7 ozs.

Warm Sepia	$4\frac{1}{2}$ minutes.
Red Chalk	$5\frac{1}{2}$ "
Brown Black	$5\frac{1}{4}$ "
Rembrandt Sepia	$4\frac{1}{2}$ "
Cool Brown Mezzotint	$4\frac{3}{4}$ "
Warm Black	$4\frac{1}{2}$ "
Ivory Black	5 "
Engraving Black	6 "
Grey Green	$4\frac{1}{2}$ "

For contrast, 6 c.c.s. (100 minims) less of "C" and shorten time by $\frac{1}{2}$ minute.

All the above figures are suitable for Platino Matt bromide papers, Wellington and Ward, Imperial, Paget, and Illingworth giving very similar results.

Wellington and Ward S.C.P. Matt (a gaslight paper) requires exactly $11/16$ of the above times.

H. F. FARMER.

TORONTO CAMERA CLUB.—Judging from the catalogue which has been kindly sent to us, the recent exhibition arranged by the Toronto Camera Club in connection with the Canadian National Exhibition was a success, both pictorially and in the interest which it attracted among photographers both in Canada and the United States. British pictorial workers were represented only by a few of the stalwarts of the Liverpool Amateur Photographic Association.

YORKSHIRE PHOTOGRAPHIC UNION.—The Yorkshire Union has just issued its handbook for 1919-20, the chief item of contents being the lengthy list of lecturers and demonstrators and of the subjects with which they are prepared to deal in addressing photographic societies. The list represents a very great variety of travel and technical fixtures, and incidentally is a demonstration of the continued energy and interest which our Yorkshire friends display in photography.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).

 Wedding Groups (Oct. 3).

COMBINATION PRINTING.

It is sometimes necessary to combine portions of two or more photographs to form one print. Although rather troublesome work, it is usually fairly remunerative, and if properly done adds to the prestige of the photographer in the eyes of his patrons. Perhaps the most usual job is inserting an extra figure in a group, and next to that the addition or substitution of a background to a figure, building, or other object. With the general adoption of bromide printing the older style of printing by means of a careful system of masking the negatives has almost fallen into desuetude, but at one time very fine examples were shown by the late H. P. Robinson, Robert Slingsby, and many others, the earliest practitioner, probably, being O. G. Rejlander, whose celebrated allegory "The Two Ways of Life" was printed on one sheet of paper from no fewer than forty different negatives. I possessed a copy of this picture, now, unfortunately, faded to invisibility, and can certify to the complete success of the method. It is hardly necessary to say that this process can only be carried out upon a printing-out paper on which the image is fully visible, so that the masks can be properly adjusted. A hint by Mr. Robinson worth repeating is that, if possible, joins should not be made on the outlines of figures; this, however, can rarely be acted upon unless the original negatives are specially made with this end in view.

An easier method, and one which I have employed with considerable success, was introduced by Mr. T. Edge. It is especially useful for small work, and only requires a steady hand and a little skill in using a sable brush. The procedure is as follows:—Supposing it is wished to place a landscape background behind a figure taken against a brick wall, the background in the figure negative is very carefully blocked out with opaque, so that it will print with a perfectly white background. A print is made upon a printing-out paper, either gelatine or collodion. (I have used most brands of P.O.P. as well as Seltona and Paget Self-toning.) The figure if small is carefully painted over with gamboge water-colour, so that all light-action is obstructed, care being taken to keep very exactly to the outline of the subject. When dry, the figure is adjusted in the desired position upon the landscape negative which is to form the background, and this is printed to its proper depth, taking care that it is rather on the light side. All that has now to be done is to wash off the gamboge with plenty of clean water

and to tone and fix in the usual way. No other colour than genuine gamboge is suitable, as not only does it leave no stain upon the paper, but it has no effect upon the unfixed image. It is, of course, necessary to paint the image over by artificial light or to use a yellow blind with daylight. If large images have to be dealt with only about a quarter of an inch margin need be "gamboged," the remainder being covered with an opaque paper mask, which may be attached to the negative with a touch of rubber solution. It is manifestly impossible to employ this method with bromide paper for contact printing, but a modified form may be used for enlargements.

The figure negative, having been blocked out so as to print with a white background, is placed in the enlarger and focussed to the desired size upon a piece of card, upon which the outline is carefully traced in pencil. This is accurately cut out and fixed upon a sheet of glass at least as large as the finished enlargement is to be. The bromide paper is next pinned up and an exposure made for the figure. This is developed with a rather weak developer, until the outline is clearly visible, and well rinsed. Meanwhile, the landscape negative is put into the enlarger with the yellow cap on; the faint image is now pinned up so that it comes into its correct position on the background, and the mask (supported on the glass) fixed up so as to protect it. There should be a slight distance between the glass and the paper so as to avoid a sharp join. The exposure having been given for the landscape, development proceeds as usual. Some practice is necessary to ensure good results and great cleanliness is needed to avoid stains. Test exposures must be made for both figure and background negatives, so that the depth of colour is evenly balanced in the combined print.

The insertion of skies and foregrounds is a more simple matter, as these may be vignetted in by means of masks cut approximately to the desired outlines. If pencil marks are made on the margins of the bromide paper to show how far the foreground and sky negatives are to be allowed to cover, it will not be found necessary to develop the print partially as a guide. If preferred, push pins may be used to mark the limits of the various exposures, but I favour the pencil marks, as it is sometimes necessary to shift the paper on the easel in order to bring the required portion of the sky into position.

The most generally practised method of combination printing is what may be called the patchwork way. This is both easy and efficacious, as there is no question of registration. Let us suppose that an additional figure is to be introduced into a group. The first step is to make a print of this figure exactly the correct size to range with the other members of the group. This is then cut out with scissors and pasted into position on the group print. If the cut edges show as white lines they must be darkened with a little spotting colour. The next step is to copy the whole thing, and to make the final prints, either by contact or in the enlarger from this negative. I have made a little modification in this process which I think has some advantages. After cutting out the figure which is to be added I soak it and the group in water until quite limp, place them together in position, and then squeegee down upon a clear piece of glass. By doing this any unevenness of surface is avoided and the join is much less in evidence; there is also a great saving in time, and no cardboard is needed for mounting. It may perhaps be useful to give details of an actual job. I received a postcard film negative of a lady reclining in a bathing dress, and an engraving showing a somewhat similar female on the edge of the surf with huge waves breaking a little further back. My task was to produce a similar effect in whole-plate size from the film negative. Fortunately a number of negatives of waves were available, and I easily found a suitable one. From this I made a 12 x 10 bromide enlargement on smooth

paper. Next I made an enlargement from the film on the same brand of paper. When these were dry I did what was necessary in the way of finishing with lead pencil. I then cut out the figure, soaked it and the wave picture and floated them into position under water. They were then squeegeed down face to a clear glass, and copied through the glass, the negative being the desired whole-plate. The whole operation, excluding drying, took about two hours.

Some very expert photographers manage to combine negatives by scratching a clear space upon one and transferring into this space a portion of film from another negative, the stripping being effected by means of hydrofluoric acid. While good results can be obtained in this way, it is not one for the every-day worker who wants to use materials and methods in ordinary use. Nor can I endorse the advice sometimes given to join up film negatives by cutting to shape and cementing upon glass. This method has given in my hands a more noticeable join than almost any other.

For the beginner I recommend the "patchwork way"; it is most generally employed for press work, and requires little practice to get good results.

There are various optical methods of combining figures and backgrounds which have recently been described in the "B. J.," but these necessitate special apparatus which the ordinary photographer will not find it economical to acquire.

PRACTICUS.

EFFICIENCY IN THE WORKROOM.

(Continued from page 576.)

When enlarging prints which require a tinted border most workers, I believe, register the print in a printing frame, arranging this in front of the easel of the enlarging apparatus.

Fig. 5.—Masked enlargement-prints made by clipping mask and paper together before placing in easel.

A much simpler and quite as efficient a way is to register mask and paper in the hand, then clip both together at one end with a strong steel paper clip, placing this in position on the easel as one piece, as shown in Fig. 5. You will find that this occupies about one-fourth of the time, and I have never known it to give a false registration.

Fig. 6 shows a piece of apparatus which is a real time saver,

one of my few original pieces of apparatus. It is a circular revolving trimming desk, and should be in every studio where large prints have to be trimmed uniform by the aid of a glass-cutting shape. The construction is as follows:—A crosspiece

Fig. 6.—Revolving desk for saving time in print-trimming.

of wood with an iron pivot in the centre, and four small rollers at each extremity, to insure smoother rotation, forms the base.

The desk itself is circular, about one inch in thickness, made of white pine with the grain crossed, and covered with thin

Fig. 7.—Construction of parts of the desk shown in Fig. 6.

sheet zinc, this metal being about the best medium for a trimming surface. Underneath the circular top piece, in the centre, is the iron counterpart of the base pivot on which it revolves. (Fig. 7.) The size of the desk I use is 24 inches in diameter, but,

of course, it could be made any size, according to the various needs of those who use it. Its chief advantage lies in the fact that you remain in one position whilst trimming, instead of having to lift your desk around or walk around the print. It requires practically no effort to revolve the print or to stop it just where required. I have been using this desk for over three years with great results, and, by actual count, it saves just one-half of the time on the old method.

A piece of apparatus which I designed for hypo-alum toning is not particularly wonderful, nor perhaps original, but is certainly very efficient. I have a double boiler arrangement in common with most studios. The stand is made entirely of iron and sheet tin, eliminating all danger of fire. There are four iron legs, three ventilated sides, and an iron door in front. About six inches under the tank which contains the jacket of water are four fairly large gas burners, capable of raising the bath to the required temperature in about ten minutes. This piece of apparatus, whilst simple, has many advantages. It can be placed in some corner of the building where the odour cannot permeate the rest of the studio. Its construction is too simple to get out of order, yet it is the most efficient thing for sepia toning that I have come across.

Not every studio gives the thought and time to the retouching equipment that this very important branch of the business deserves. But all studios are very careful to expect and demand the best of their retouchers, no matter the conditions under which they work. In many cases the retouching has to be done in some little hole of "sardine-like" space. I know of one instance where the retoucher has to work so close to the roof of the building that if he should forget himself and stand up, the contact of roof and head would severely remind him of his mistake. Also, how many desks are put together so temporarily that a good sneeze would blow them over? The conditions are immaterial, we say, so long as the work comes through.

But with a retouching desk that is clean and substantially built, and with working conditions as comfortable as circumstances will permit, the negatives arranged in convenient shelves close at hand, you eliminate the former handicap, and your retoucher cannot but give you the best that is in him. These few points are very essential, as faulty retouching is responsible for many unsatisfactory pictures, and no workman can give you his best unless he has full help from his apparatus.

The desk which Fig. 8 describes costs only a few shillings, and a few hours to build. It is substantial, clean, and allows

Fig. 8.—Bench of retouching desks, with shelves above for negatives, etc.

plenty of working room. It consists of two lengths of ten-inch board fastened together, with convenient openings for negatives. This is placed at the required angle on a baseboard about 18 inches from the wall and 2½ feet from floor.

Sufficient space is provided for elbow rest, and a leather strap is fastened vertically on both sides of the negative opening, and stretched as tightly as possible. If a piece of lattice wood is slipped under these two straps the negative to be retouched can be placed in any position required. These straps can also be used for holding pencils, etching knife, etc., when not in use.

There is an arrangement in connection with this desk which might be of interest to some of you, although I question whether one in a hundred would find a need for it. The arrangement

I refer to is a quick method for changing a daylight desk into one for artificial light. For the benefit of those who may have a need for it I will give a brief description.

Behind the sloping desk, and fixed on the base of the retouching stand, is a double track (Fig. 9) on which runs a board with electric brass socket attached. This socket is fitted with an automatic switch. When the daylight becomes too poor for

Fig. 9.—Electric-light fitting for retouching desk.

retouching the retoucher pulls a cord to his right underneath the desk. This runs the electric bulb in the base socket along the track until the point of contact is reached. The light is then automatically switched on behind the centre of the negative to be retouched. A cord on left reverses the action, breaks contact, and prepares desk for daylight work.

I may add that I have found opal glass an excellent medium for retouching by artificial light, and, fitted to the platform, with base socket, on the same angle as the desk, is an 8 x 10 piece of opal (Fig. 10) which, of course, moves with the bulb, and is in position behind negative when light is on.

Fig. 10.—Opal-glass diffusing screen shown for the fitting of fig. 9

Mounts, and their keeping, is a vexed question with some photographers. Many a mount salesman owes a big sales report to the fact that photographers have over-ordered, because, owing to systematic arrangement of the mounts, they were not aware of being over-stocked in some lines. System in keeping mounts is very important. We keep each line of mounts together—in their boxes—and in cupboards with doors that are always closed. Cleanliness with mounts is also an important point.

In connection with this subject of mounts, I am illustrating a mount chart (Fig. 11) which is simplicity itself, and which will be found an infallible guide to the number of mounts in stock. The first column of this chart contains a description of the mounts in use, their size, colour, etc. Each size, each colour, occupies one line.

The next column is devoted to the number of mounts in stock say, since January 1, when inventory is taken. Now if the finisher will carry out faithfully the rule to subtract from the

former total on chart the number of each box of mounts as they are opened, the last total of each mount will be the present total in stock. Thus, when the salesmen make their call, it is not necessary to take an inventory of mounts. I have only to take a glance at my chart, and I can tell in a few moments what to order, and what is just as important—what *not* to order.

This chart will remove the anxiety of running short, and also save the frequent overhauling to see if one is sufficiently

MOUNT SUBJECT	MOUNT CASES TOTAL OF EACH CASE IS OPENED

1/27 200mm	100	50	20	10	5	2	1	1	1	1

Fig. 11.—Chart for records of mounts in stock.

stocked in all lines. If kept with dates, such a chart will prove a splendid criterion of the relative popularity of the various mounts, and if one or two styles of mounts are not being used as fast as they ought, the receptionist might be asked to make a special inducement to speed up the sale of these. A separate cupboard should be used to keep mounts that are in daily use, and as each box is opened its entire contents should be checked off the chart and placed in this cupboard, and the box thrown away. This will remove the confusion of having full and half empty mount boxes stored together.

An idea which I have recently invented, with some success, greatly simplifies the process of embossing. Prints that have been printed with a tinted border are usually selected for embossing. These prints have, of course, to be registered exactly during printing, and it is upon this principle that my embossing idea is based.

HERBERT G. STOKES.

(To be continued.)

STORING SENSITIVE PAPERS.

(From "Rajar Trade Notes.")

WITH the advent of dull, damp weather we would impress upon our business friends the importance of providing for the proper storage of sensitive papers. Bromide and gaslight papers possess astonishing keeping properties if certain precautions are observed.

The careful stock-keeper who uses shelves and cupboards for the storage of sensitive papers should arrange for the papers to be placed on the lower shelves as near the floor as possible. It is asking for trouble to place them on a top shelf in a room lit by gas or warmed by a coke stove. The golden rule to observe is to keep all sensitive papers well away from the products of combustion, and in a cool, dry place.

Dampness will also cause sensitive papers to deteriorate rapidly, and in the case of bromide and gaslight papers the emulsion may become locally de-sensitised. In some workrooms a practice is made of exposing bromide prints and delaying development for a day or two, but this is a method which we do not recommend. We made some experiments in this direction, and found that bromide prints exposed one day and developed a few days later did not give anything like such good results as usual, especially those that had previously been stored in a damp place. The latent image appears to lose a large amount of the depth impressed upon it by light-action. With exposed plates and films this is not so apparent, excepting in the case of damp storage.

"Stale paper" is often the verdict given on paper that shows

the characteristic discolouration of the edges, whereas the real reason is invariably "bad storage."

Sensitised plates and papers should never be stored in a room where sulphide or hypo-alum toning is done, or, in fact, anywhere near where sulphide fumes are likely to be present.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Self-Training in Drawing.

I suppose every photographic assistant realises how useful a little skill in drawing is to him or her. In many ways, if only a little; much more, if you attain some proficiency. Yet many say, "I can't draw at all. I'm afraid I can't learn, and there is no art-school I can go to." Never mind, a beginning, if you work on the right lines, is better than doing nothing, and therefore I will try to explain how to make a start in teaching yourself.

You need not have any very expensive outfit. A fair-sized drawing board, a few pencils, drawing pins, and a few sheets of drawing paper and a piece of rubber are all you need to start with. An H.H.B, B and 2 B pencil will be ample. Concluding that you know nothing of drawing, a few very simple household articles will serve excellently to begin on. Begin on a book, broadside on, standing, lying flat, turned cornerwise and edgewise. Then you can go on to a tumbler, a teacup, cup and saucer, a kettle, saucepan, watering pot, teapot, jug; and then begin to arrange these in groups of twos, threes, and so on. I may say in passing that this is actually the practice in all art schools, who long ago found that these homely models are the best. None of these need you buy, of course, and all houses contain such things as candlesticks, vases, and so forth, which again answer beautifully for both black and white work and all early stages of colour work.

In practice, stretch a sheet of paper, arrange your model, say a kettle, on a sheet of brown paper a few feet from you (if possible nearly on a level with your eyes), and start work. You can sit in, one chair and rest your drawing board on the back of another, or on a chair turned upside down—this also is done in the schools. Take your H.B or B pencil and roughly tick off the size of the space you wish your drawing to fill, taking care to keep your drawing to a good large size. Now in starting to draw or paint, try hard to keep in mind one great rule; i.e., that you are out to set down on paper just what you see, quite irrespective of what you know to be there. This is just exactly what the camera does; therefore, if you are going to use your drawing knowledge, say, to help you work up a good big enlargement, putting in a fresh background, you have only to go to work in just the same way, and you will find that you will get along swimmingly, and not turn out those ridiculous effects one often sees in woefully cheap and poor enlargements, and which really do give one quite a bad pain ever to look at.

To get your proportions, hold your pencil out at arm's length, against the model, close one eye, and mark off with the thumb the apparent measurement on the pencil. Compare the various parts one with another—you will perhaps thus find the height to be just 2½ or 3 widths—and thus you can get your proportions true. The angles made by retreating lines can be gauged by holding one pencil upright and one right across it at right angles, for retreating lines are most deceptive things.

Sometimes it is good to trace with the pencil, keeping one eye closed, the outline of the model you are drawing, for thus you will discover to your surprise how greatly the apparent shape of the model differs from the actual shape. The top of a cup and saucer you know to be round, but on tracing it you find that it has become greatly flattened, narrowed, and elongated. Well, don't worry, just set down as accurately as you can just what you find you are seeing, and you will be surprised how soon you will find yourself making quite decent recognisable drawings.

Learn above all things to see. Study your model carefully before putting pencil to paper. You will find that the shape, the light, and the way the light strikes all make up together the mass you see. Again, one edge is light, one edge is dark; one edge seems to

melt away, the other stands out sharp and clear. Well, this you must learn to imitate, too. You must learn to "accent," as it is termed. To do this use a soft pencil, with very light pressure at the light edges, and gradually increase the pressure where the edge is sharpest and darkest. Usually, accenting is thought to be most needed on the right-hand side, and nearest to the eye of the artist. This is, of course, when the ordinary lighting falls on the model—from above, and to the left: if the lighting is different, accenting will be needed in different parts. At any rate, a very little practice and a few trials will soon show you the difference "accenting" makes to your outline drawing. Instead of even sweeping lines of unvarying thickness you at once begin to put life and character into your drawing, and to redeem it from flatness. Study any portrait or landscape print and you will see that no matter whether studio or out-of-door lighting each photograph contains just this difference in the quality of the edges, and if you strive to match this in your working up, either on print or negative, you are bound to do good work, and your drawing be of much benefit to you.

In practice, try and make long, smooth, swinging lines on your paper; don't bore the point of your pencil into it, or you will never succeed in rubbing out any incorrect lines. First plot in lightly the proportions and outline of your drawing, then after a few minutes' rest examine critically, and if it satisfies you, go carefully over it, rounding off, accenting, and doing all you know to make it as accurate as possible. Now leave this drawing a couple of days, and then take it up again. Hold it in front of a mirror, and look carefully to see where your drawing is faulty. If possible, put it side by side with the model, stand back some few feet, and compare one with the other. Of course, if you can get some experienced person to criticise it for you, it will be even better. But do impress this on your mind from the beginning, that the only way in which anyone ever learns to draw is by making drawings, many and varied, taking all the care possible, and yet making mistakes. Don't despair; these very mistakes are the things you learn most by, for one finds that the most important things to know are what things *not* to do, and incidentally *how not* and *what not* to draw. Peg away a few hours a week; for three months will do wonders for a novice who is really in earnest.

A very useful few minutes may be spent in this way. Take an empty C. de V. plate box, or anything nearly square, hold it down below your waist, and note the true square shape of the top. Now gradually raise to above the eye level, and watch how this shape appears to alter. Now try a teacup in the same way. From being square, one becomes diamond shaped, and then only an outline, while the other changes from a true circle in the same manner. Of course, their real shape is unaltered, but we thus see what we should put on paper when drawing them. This is what we term "foreshortening," meaning the apparent alteration of shape as seen by the eye, and as also recorded both by the draughtsman and the camera.

When you can draw readily and easily any shape you see, try shading them. Watch through half-closed eyelids for the broad masses of light, shade, and shadow. Later, you will learn to call them high-lights, half-tone, and shadow. The easiest way to learn is to work with fairly soft charcoal, on charcoal paper with big broad touches even and steady, following with your strokes the direction in which the light falls. Then again work with a soft pencil, and then try stumping your chalk and stumps, working for smooth masses, blending one into the other as softly as possible, and watching most carefully for the high-lights and half-tones. As an additional help, these may be picked out with soft putty rubber, knedded to a point, or with a little slip of stale bread. In this sort of work you cannot help noticing how like it is to retouching and the working up of enlargements, and this to a photographer is its great use.

Charcoal is supplied in sticks, sharpened to a point, and used in a little metal holder, for convenience and cleanliness. Stumping chalk is supplied in different colours in little glass tubes tightly corked. Stumps of assorted size, both leather and paper, are the most useful. None of these tools cost more than a few pence.

Both geometry and perspective form part of the drawing course, and though at first sight they simply bristle with appalling names, etc., taken section by section, in small doses, these resolve them-

selves into very useful rules, and lose all their terrors. A very useful little manual used by art schools is Carroll's "Complete Geometry for Art Students," and for perspective Dennis's "Complete Perspective Course." There are two little books some students might like in Cassell's series, "How to Draw from Models" and "How to Shade from Models," by Sparkes. Then there is the drawing manual issued from the B.J. Office, which is also excellent. There are also other books on the same subjects, but these I am not well acquainted with. Those I have mentioned are all on the South Kensington list.

If any students wish to obtain models or plaster casts (and these are most useful to study drawing of faces, eyes, ears, nose, mouth, etc.) these can be obtained from half a crown and upwards from Messrs. D. Brucciani and Co., 254-8, Goswell Road, London, E.C., who issue an excellent illustrated catalogue which will be a most useful guide as to what to order. I have, of course, been able in this brief article only to skim over the surface of the subject, but most of all I would like to impress that the only way to learn drawing is to keep on drawing. It may somehow sound formidable as I have described it, but if one or two students can work together much fun and real enjoyment may be got even out of mistakes and failures. But the first basis of black and white drawing must be well and truly laid. I have watched Royal Academy exhibitors at work oftentimes, and many people would be surprised, I have no doubt, if they could only see the care and thought expended on the first drawing, before any touch of colour is put on. Here I would like to point out that to the photographer his knowledge of drawing has to supplement the work of the camera and enlarger, and often to fill up lamentable gaps, so that to him a practical working knowledge of drawing is every whit as necessary as to the artist. Moreover, it stamps his work with an indefinable something which marks out the high-class from the middle-class assistant, and in practical results it makes quite a big difference in the number of currency notes the assistant can expect to receive yearly for his work.

G. E. H. G.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- REFLEX CAMERAS.—No. 23,756. Reflex photographic cameras. P. G. Mason and Newman and Guardia.
- PHOTOGRAPHY.—No. 23,570. Photograph and process for producing the same. T. S. Mercer.
- STEREOSCOPIC VIEWING APPARATUS.—No. 23,237. Apparatus for viewing stereoscopic cinematograph, etc., pictures. A. K. Maxwell.
- LENSES.—No. 23,235 23,236. Lenses. H. W. Lee and Taylor, Taylor and Hobson.
- LENSES.—No. 23,726. Preparing lenses for grinding and polishing. W. Taylor.
- LENSES.—No. 23,287. Lenses. A. Warmisham.
- CAMERAS.—No. 23,731. Bellows cameras and fittings. T. W. V. Webb.
- SOUVENIRS.—No. 23,366. Photographic souvenirs. W. Buckstone.
- PHOTOGRAPHIC APPARATUS.—No. 23,555. Apparatus for photographic enlarging, printing, and copying. J. E. Bramwell.
- PRINTING.—No. 23,718. Printing apparatus for production of diapositives. S. de Prokudine Gorsky.
- COLOUR PHOTOGRAPHY.—No. 23,256. Manufacture of coloured photographic pictures. J. H. Christensen.
- COLOUR PHOTOGRAPHY.—No. 23,531. Natural colour photography. R. Wellesley.
- CINEMATOGRAPHY.—No. 23,418. Cinematograph cameras and machines. V. Keating.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TELEPHOTO LENSES.—No. 132,067 (September 23, 1918). The invention relates to telephotographic objectives—i.e., those in which

the focal length is considerably greater than the distance from the back glass to the focal plane, or the so-called back focal length. The ratio of the former to the latter will be spoken of as the magnification.

The invention consists in improvements, the aim being to obtain a large, useful field and aperture, together with greater magnification than has hitherto been obtained with good correction. The manner in which this improvement can be obtained will now be shown.

To obtain a flat field of any extent it is essential that the system should fulfil the so-called Petzval condition; that is to say, if F is the power of a lens or single surface and n is the refractive index of the glass of which the lens is made, then the sum of the quotients $\frac{F}{n}$ for all the surfaces of the system must be zero or small. In ordinary photographic lenses this sum should be a small positive quantity. In telephotographic systems it should generally be a small negative quantity. It is by making this value of suitable size that flatness of field in any optical system is arrived at. In the present case it is obtained by the choice of suitable glasses, whereby at the same time a large magnification is possible.

Other means have been used to obtain correction of astigmatism with more or less flattening of the field, such as, for example, those described in patent No. 3,096 of 1914 ("B.J.," December 4, 1914, p. 890), where the correction of astigmatism is arrived at by using an air space between the lenses of the front combination, which space can be varied till the required correction is obtained; and those claimed in patent No. 1,185 of 1914 ("B.J.," April 23, 1915, p. 273), where a less perfect correction is obtained by the use of a different set of glasses from those now proposed to be employed. In both cases the magnification does not exceed two. In the arrangement described in patent No. 19,580 of 1909 ("B.J.," January 14, 1910, p. 30), a larger magnification is attained, but with no attempt at fulfilling the Petzval condition, so that the field is small and very much curved in the sense associated with a dispersive lens; again, different glasses are employed.

Calculation shows that the ends above enumerated, viz., freedom from astigmatism, flatness of field, and large magnification, together with the usual corrections of spherical and chromatic aberration on and off the axis, and coma, can be attained by, and the present invention consists in, making the front component of a telephotographic objective of a double convex crown of medium refraction and dispersion (specified herein in the usual manner of the glass makers by $N_D = 1.573V = 57.5$) with a double concave flint lens of considerably higher refractive index as well as dispersion ($N_D = 1.621V = 36.1$, or, better still, $N_D = 1.652V = 33.5$), the difference of refractive index being at least .04, and preferably greater. The back component would be triple and would consist of a double convex lens of as low a refractive index as is consistent with high dispersion ($N_D = 1.55V = 45.8$) between two dispersive lenses of high refractive index and low dispersion ($N_D = 1.61V = 59$), of which the inner (i.e., that towards the front) is double concave and the outer is meniscus. It is essential that the lenses should have these shapes and that the difference of refractive index should be

at least .06 (or more, if any improvement in glass manufacture should make that possible). With this choice of glasses, by strict computation, it is possible to restrict the shapes so that all the glasses in each component (two in front, three in the back) shall be cemented together.

The invention will be further elucidated with the aid of the

subjoined specification and with reference to the drawing, which is a diagrammatic illustration of a telephotographic objective constructed and arranged according to the invention, and showing the relative positions, curvatures, and thicknesses of the front and back components of the lenses composing the objective.

The specification alluded to is for a 12-in. lens of magnification 2.5 and aperture $f/7$:-

FRONT COMPONENT.

Radii.	Thicknesses or Separation.	Refractive Index N_D .
r_1 1.9	d_1 .36	L_1 1.573 V 57.5
r_2 3.197		L_2 1.652 33.4
r_3 8.632	d_2 .07	

BACK COMPONENT.

Radii.	Thicknesses or Separation.	Refractive Index N_D .
r_4 1.23	s 2.47	
r_5 2.9	d_3 .06	L_3 1.611 59.0
r_6 .972	d_4 .24	L_4 1.55 45.7
r_7 2.47	d_5 .06	L_5 1.611 55.0

The claim made for the invention is:—A high magnification telephotographic lens of wide aperture and large, useful field, free from astigmatism and curvature of the field as well as spherical and chromatic aberrations, by the use of cemented components of which the front is achromatised and consists of a double convex lens of medium barium crown, the index of refraction of which is 1.573 ± 0.005 , and a double concave lens of dense flint, the index of refraction of which is at least .04 greater than that of the double convex lens, and of which the back, also achromatised, consists of a double convex lens of refractive index 1.55 ± 0.005 between two dispersive lenses of refractive index at least .05 higher than that of the convex lens, the outer dispersive lens being meniscus in shape. Horace Lee, B.A., and Taylor, Taylor and Hobson, Ltd., both of Stoughton Street Works, Leicester.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

ARISTO.—No. 391,378. Photographic papers. Kodak, Limited, Kodak House, Kingsway, London, W.C.2.

CHRISTMAS POSTCARDS.—Messrs. Criterion, Ltd., Stechford, Birmingham, remind us that they are issuing Christmas greeting sensitive postcards in the various grades of their emulsions. The designs occupying the left-hand space of the face of the cards are printed without extra charge.

EASTMAN RESEARCH LABORATORY.—The temporary suspension of publication of communications representing the results of photographic research by the staff of the Eastman Research Laboratory has no doubt had its origin in the concentration of Dr. Mees and his collaborators upon problems connected with the war. That such is the case is indicated by the appearance of a lengthy paper on protective colouration as a means of defence against attack by submarines by Loyd A. Jones, of the laboratory's staff, which occupies twenty-five pages of the current issue of the Journal of the Franklin Institute.

A CALIFORNIAN SALON.—The third International Photographic Salon under the auspices of the Camera Pictorialists of Los Angeles will be held in the Gallery of Fine and Applied Arts, Museum of History, Science and Art, Exposition Park, Los Angeles, California, from January 3 to 31, 1920. The aim of the Salon is to exhibit only that class of work in pictorial photography in which there is distinct evidence of personal artistic feeling and execution. All work submitted to the jury of selection will be carefully and impartially considered, but no picture will be eligible which has been previously exhibited in Los Angeles. All pictorialists are cordially invited to contribute. Address all correspondence and entrance fee to Ernest Williams, Secretary, Room 31, Walker Auditorium, Los Angeles, California.

FORTHCOMING EXHIBITIONS.

- September 13 to October 11.—London Salon of Photography.
Hon. sec., 5a, Pall Mall East, London, W.C.1.
- October 13 to November 29.—Royal Photographic Society.—
Entries close September 19 (carrier), September 20 (hand).
Secretary, J. McIntosh, 35, Russell Square, W.C.1.

New Books.

"The Marvels of Photography." By Charles R. Gibson.
London: Seeley Service and Co. 5s. net.

UNDOUBTEDLY there is a large public among those who practise photography, and equally among those who do not, which is interested in photography itself—that is to say, in its evolution and in the various applications which it has received. Obviously a book which is to make a successful appeal to a wide circle of readers requires to be written in a light and popular style, and from this standpoint one would have to go a long way to find an author better qualified for his task than Mr. Gibson, who is known also by a large number of other books in which some branch of science or industry is popularly treated. In dealing with photography Mr. Gibson has commendably kept close to its historical development. He tells us in a very conversational way of the early efforts of Niépce and Daguerre, and proceeds then to trace the progress of photography along the lines of the discoveries of Fox Talbot and Scott Archer. In dealing with colour photography he pursues a very similar plan, and is at pains to make clear the basis laid by Mr. Ives for processes of three-colour photography. If we have any criticism to make of this part of his work, it is that we miss the names of Clark Maxwell and Ducos Du Hauron; but it must be remembered that the author's aim is evidently to promote a broad comprehension of photographic processes and the lines of their development by bringing vividly before the reader certain specific achievements which are typical of a given process or system. Thus there is the temptation—or perhaps we should say, the necessity—to steer rigidly along this course and to refrain from overloading the vessel with cargo which the more superficial reader cannot be expected to examine. One of the most comprehensive sections of the book is that dealing with the photo-mechanical processes—that is, with the making of line and half-tone typographic blocks and with collotype and photogravure printing processes. Even to many of those who are familiar with ordinary photographic processes these are unfamiliar realms, in the exploration of which Mr. Gibson shows himself an agreeable and well-informed companion. A chapter is devoted to the use of photography in the detection of crime and identification of criminals, whilst the last part of the book deals with X rays, the action of radio-active substances on photographic plates, and with the marvels of photo-micrography. It is within our experience that the need of such a book as this is felt by many photographers on the occasions when they are asked to give some short and popular discourse on the origin and development of the art. In cases like this the man who may know all that needs to be known about sulphide toning or tank development is hard put to it to make such knowledge of interest to a general audience. He has to go back to the early days of photography, and, moreover, has to catch the spirit of romance which is to be found in every industry or science by those who will look for it. Mr. Gibson traverses the historical field, and in this spirit, so that his book, the contents of which are taken, so we learn, from his larger and more expensive volume entitled "The Romance of Modern Photography," is just what can be recommended to those whose knowledge of photography is limited to the working details of present-day processes.

THE MARVELS OF PHOTOGRAPHY.—Our publishers inform us that they are special selling agents of the volume "The Marvels of Photography," by Charles R. Gibson, just issued. The book is sent post free, inland or abroad, for 5s. 6d. on application to Henry Greenwood and Co., Ltd., 24, Wellington Street, W.C.2.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Notice is given that the partnership between Percy Joseph Coles and William Arthur Crane, carrying on business as commercial and architectural photographers at 46, Imperial Buildings, Dale End, Birmingham, under the style of Coles and Crane, has been dissolved by mutual consent as and from September 1 last. The business will in future be carried on by Percy Joseph Coles, at the same address.

NOTICE of intended dividend is given in the estate of Henry Arthur Yvery Heathcote (described in the Receiving Order as Arthur Heathcote), photographer, 22, St. James' Street, Piccadilly, W., and lately carrying on business there. Proofs must be lodged on or before October 11, with Henry Fraser, chartered accountant, 1, Guildhall Chambers, Basinghall Street, E.C.

NEW COMPANIES.

MEADOWS OPTICAL CO., LTD.—This private company was registered on September 25 with a capital of £5,000, in 4,000 8 per cent. cumulative preference shares of 5s. each and 4,000 ordinary shares of £1 each. To carry on the business of manufacturers of and dealers in all kinds of scientific instruments, optical materials, photographic requisites, and engineering instruments, etc. The subscribers (each with one ordinary share) are:—H. W. Meadows, 62, Pemberton Gardens, Upper Holloway, N.19, optician; H. H. Meadows, 79, Ealing Road, W., optician. The first directors are: H. W. Meadows and H. H. Meadows (managing director). Qualification, 1 share. Registered office: 188, Junction Road, Upper Holloway, N.19.

News and Notes.

OSRAM HALF-WATT LAMPS.—The General Electric Co., 67, Queen Victoria Street, London, E.C., sends us a schedule showing the reduction just made in the prices of half-watt lamps. The 1,000 c.p. half-watt has now been reduced in price from £2 to £1 10s. A folder issued by the General Electric Co. shows the powers and voltages of the full series of half-watts which are obtainable.

A BARNET OUTLOOK.—A four page circular just issued by Messrs. Elliott and Sons, Ltd., and addressed to professional photographers, contains a reminder that the firm's manufacturing staff have now returned to their old posts from service in the army, and that the company has been strengthened by the appointment to the commercial side by Mr. F. W. Greenwood, who will assist his father, Mr. F. E. Greenwood, in a vigorous campaign of improvement and extension of trade.

THE CITY SALE AND EXCHANGE has just issued from its latest branch—namely, that of 105, Cannon Street, E.C.—a forty-four page list of secondhand apparatus of all descriptions, including a great variety of vest-pocket and reflex cameras, focal-plane cameras, roll-film and other hand cameras, in addition to the larger items of equipment in the way of field and studio cameras and enlargers principally required by professional photographers. This list may be obtained from the branch, opposite Cannon Street Station, or by postal application.

PHOTOGRAPHIC DETECTION OF CAMOUFLAGE.—A paper by Mr. H. M. Stillman, before the American Physical Society, describes a method worked out for detection of camouflage. The method consists of making two negatives of approximately equal density of the group of objects, one before the change, the other after the change, printing a positive from one of the negatives, and then superimposing this positive upon the other negative. When these photographs are properly made, those parts of the picture which have not changed in the interval between exposures will show up as a field of practically uniform density, while the changes are clearly shown up by a considerable departure from this uniform density. When it is impracticable to make the scale of the original negatives the same, as in aircraft work, results can still be obtained by enlarging or reducing, by matching the negative with the projection of the positive, or vice versa. This method has long been in use in astronomy for the detection of variable stars. It was independently devised by a member of the Bureau of Standards staff and developed for camouflage detection, engineering, and other purposes in co-operation with Captain H. E. Ives, of the United States Air Service.

A DRYING CABINET FOR NEGATIVES.

To the Editors.

Gentlemen,—*Re* your article in the B.J. Almanac, 1918, p. 256, I have had serious mottling through irregular drying, but since reading your article have made a cabinet with great success. On top of cabinet I used an old incubator kerosene lamp. I covered it with a kerosene tin and piece of 3in. downpipe soldered on. Although I put in plates at bottom to warm the air, I have found it unnecessary to use them, as without touching negatives with a cloth or chamois, merely shaking vigorously, they dry perfectly and evenly in from 1½ to 2 hours, and this with cabinet on a verandah with outside temperature registering 10° of frost.

This method never entered my head until I read your article. It is a wonder that no firm has put this simple method on the market in a practical manner.

Wishing your Almanac every success.—Your faithfully,
JAS. S. THONEMAN.

Kuyura, Dalby, Queensland.
August 14.

SENSITISING CANVAS.

To the Editors.

Gentlemen,—The best method of making photographic prints on canvas (and it is really the only one known that fulfils the artist's requirements) is one practised as a secret process for many years by Mr. A. Brothers, of Manchester, and published by him in his "Manual of Photography" in 1889. The method is as follows:—The canvas is wiped free from dust with a soft cloth or a damp wash-leather; it is then coated with—

Calcium chloride 60 grs.
Methylated spirits of wine 5 ozs.

This is rubbed well into the canvas, using a pad of swansdown,

continuing the rubbing until all tendency on the part of the surface to reject the solution is quite overcome and the surface is moistened quite evenly all over. Finish the drying in front of a fire or, indeed, close to any heat-source.

When dry rub over with another pad of swansdown dipped in—
Silver nitrate 320 grs.
Water 3 ozs.

When evenly coated, dry, then print under the negatives, using daylight or light, mercury-vapour or half-watt. The exposure is fairly rapid, say, for a thin M.Q. developed negative in good daylight 10 to 15 minutes, direct sunlight 5 minutes, 3 feet away from an open arc 5 minutes, 1,000 c.p. half-watt 3 feet away 15 minutes. One deep tint on a Johnson's actinometer may also be taken as a guide for a thin negative.

When exposure is complete wash for a minute or two in running water, drain, and flood with—

Ammonia 1 oz.
Water 5 ozs.

Apply for three or four minutes, then wash again and hang up to dry.

Perhaps to many the great drawback to such a process is the fact that an enlarged negative is necessary, but if the Kodak Transfertype paper be used an enlarged negative can be made quickly and cheaply.

My plan was this:—For a canvas 24 × 20 I had a board 18 × 15 and ¾ in. thick. On this was fixed with thick glue a sheet of thick felt, edges cut flush with edges of board. This board was laid under the canvas and fitted well inside the stretcher (corner wedges being removed).

From the small negative make a transparency by contact if half-plate or less; if larger, in the camera. This transparency is placed in the enlarger and an enlargement made upon Kodak Transfertype paper the size required. This is developed, fixed, and washed, as directed in the sheet of instructions given with each packet of paper.

After the enlargement is washed it is transferred to a sheet of plate glass (in my case 21 × 17), and when dry this is used as the negative for printing the image on the canvas prepared as above stated.

This method of printing an image upon canvas is the only perfect method known. The coating on the canvas is itself sensitised, and that without disturbance or alteration, also without any film being superposed to interfere with the artist's brushes or paints.

The method of making a sufficiently good negative on Transfertype paper is simple, certain, and easy so long as the transfer to the glass is done without a preliminary drying of the enlargement. Drying always introducing an element of uncertainty as to whether the backing paper will stick tight or bring with it some of the image, but when this drying is omitted then there is never any trouble.

Once the print on the canvas has been made the negative may be scrubbed off and the plate-glass used for another.

"OLD PHOTO."

A COMMON CAUSE OF LOSS OF BUSINESS.

To the Editors.

Gentlemen,—That haphazard methods of conducting their businesses were fairly common among photographers of the old school must be admitted, and not infrequent failures, the inevitable consequence; but that such methods should exist to-day points very clearly to the difficulty of the "photographic temperament" assimilating the stern business qualities so essential to present-day success. Consequently, the letter by Mr. W. E. Debenham pointing out cases of photographers failing to execute their orders according to promise through lack of a simple office system, creates no surprise.

Yet why such should exist is almost beyond comprehension, as a casual glance at any photographic dealer's catalogue will reveal that all are ready to supply on demand a multiple of book-keeping and card index systems, any one of which, properly instituted, would prevent such flagrant business blunders referred to in Mr. Debenham's letter

I have had much experience of photographers' day books and

ledgers, many of which are complicated worries, others a jumbled record of words and figures, and some showing the proprietors as having a real grip of the essentials of office routine, but never once have I seen a system of books which in themselves enables one at a glance to state definitely any given order to be in a particular state of progress at any given moment.

To photographers having troubles in keeping touch with orders from date of receipt to completion I strongly recommend the introduction of the card index system, which may be supplementary to existing book-keeping methods until such time that the simplicity of the new system becomes familiar, when at least the cumbersome, useless ledger may be dispensed with.

Some years ago I experienced the worries of not keeping faith with customers by completing orders according to promise (a none too easy matter at any time where the class of work is carbon and

At the time of sitting the details of size, printing, process, mounts, and all other particulars are written on card, which becomes a permanent record of customer's order. Date of proofs promised should be inserted near bottom of card, negative numbers may be written on card or at the time of numbering negatives, according to custom, the better practice being to allot negative numbers at time of sitting. Rule a line an inch from bottom of card, and in the bottom space insert the amount of order, if known, on one side and the cash payment (if any) on the other side, which constitutes a check on your cash book, and obviates the necessity of entering in detail each customer's account in cash book; the day's cash takings may thus be entered in cash book as one sum.

It should be noted that casual sitters and everything requiring proofs should be treated exactly as "appointments," as the system will explain. The card is now placed in the file marked "Proofs."

On receipt of order further particulars are written on card and date of completion promised plainly marked, also any cash payments made, the card then being filed under "Orders."

Order Card.—A second card, say yellow, bearing fullest particulars of printing and finishing is sent to the printer. The date of completion should not be stated, but a date at least one day before date promised should be very plainly marked.

Thus, the printer sorts his orders in accordance with dates, passes card, bearing date and his initials, with prints to mounting or finishing rooms, where, again, the order is noted on a list of daily orders to be completed, and according to time due the completed order is sent for dispatch.

Special Orders.—There is nothing like colour to arrest the eye, therefore the yellow card should not be used for urgent proofs or orders, but a distinct colour, pink or blue, should be used; and when the printer gets into the way of the system he will automatically observe the special colour, which gives him no excuse of overlooking a special, and the same applies to other departments. At first sight this second card may appear to be extra office work, but it is exactly the same as entering up a printer's daily order book.

On dispatch of order, if paid for, the white card may be finally filed, for which purpose old half-plate boxes may be used, marked alphabetically. The yellow card may be destroyed, or sent to printer to be stored with negative, which latter is a good plan for future reference.

Returns Book. Should the proprietor keep a record of weekly business done, the white card is not immediately alphabetically filed, but placed in "Completed Paid File," and once a week an entry is made in the "Returns Book" either showing gross takings, from totals on cards, or set out in separate columns, headed sittings, colourings, enlargements, etc., each column being cast separate and a cross cast being carried to a totals column with a separate column for the corresponding week the previous year. The cards may then be finally filed.

This is a splendid plan, which enables a photographer easily to see what branch of his business shows paying returns, and incidentally where he may make improvements.

Completed Unpaid.—When an order is completed and the account not paid the white card is filed as "completed unpaid."

The cards, being always before the eyes of the proprietor, are a constant reminder that the accounts are to be collected. How different from a shut-up ledger!

The file "Sundries" explains itself, and the waiting order file is only a suggestion that any number of files may be made.

Enlargement, etc., should always be treated as "Orders," and filed accordingly.

Having outlined the card index system, attention is directed to the importance of its daily working.

Whoever is responsible for the office routine will at the beginning of each day examine each file, sending to the printer a list of specials, proofs, orders, etc., required for the day, which regulates the yellow card system. The printer having completed these as per prior yellow or special card, he will initial and date, and pass to finishing department, who will deliver the goods. This is the working of a simple system: all running about avoided, all bother saved, and, above all, faith kept with customers.

October 1.

A. GANDY.

platinum printing), when I happened to read in the "B.J." an article strongly advocating a card index system, which I immediately adopted with the gratifying result that I was not only able to meet my customer with the pleasing reply, "Madam, your order is completed," but also able to tell in a few minutes my absolute position to the minutest detail.

In advocating this system, it is not necessarily implied that, as hereafter described, it is directly applicable in every detail to all and sundry, as in each business it will be found advisable to adjust and title each file to meet the requirements of the class of business done. Nevertheless, the system remains intact.

The matter of cost will be uppermost in adopting any system of book-keeping, but as the card index system needs but the outlay of a few shillings the cost is but a nominal one, and the storage files can be made from waste mounts and discarded plate boxes.

With a few waste mounts a box for holding daily files can be made. A convenient size would be to make a box with a sloping inner bottom sufficiently deep and wide to take cards half-plate size (as in figure).

Cut a number of pieces of card half-plate size, title them to suit your requirements, and your file is ready for use.

A stock of thin cards of three or more distinct colours should now be procured, cut an eighth of an inch smaller than the file cards, and your card system is complete.

On the making of an appointment, whether verbal or letter, the name, address, and particulars, if any, is written on top of card, and card then inserted in file marked "Appointments."

Assuming a white card is chosen, white cards are adhered to for use in the file cabinet "only."

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- P. E.—If you make your offer generally to the public you certainly require a licence, and if the business is in London you should apply to the Secretary (New Business Licences), Iddesleigh Mansions, London, S.W.1
- R. and Co.—The latest list of names and addresses of photographers in Great Britain is in Kelly's Directory of the Chemical Industries, published by Kelly's Directories, Limited, 182-184, High Holborn, London, W.C.2, price 25s.
- J. S.—If you deal only with photographers in the way of doing printing or outdoor jobs for them and are not accessible to the public you do not require a licence, but if you put out a sign of any kind or display specimens in such a way as to invite the public, then you require a licence, which you should apply for to Iddesleigh Mansions, Westminster, S.W.1.
- J. H.—1. A saturated solution of sodium carbonate is one containing as much sodium carbonate as can be dissolved in water at a given temperature. To make a saturated solution dissolve, say, six ounces of soda carbonate in 20 ounces of hot water, and let the mixture get cold. A considerable quantity of the soda carbonate will crystallise out in the solid state: the liquid part of the mixture is the saturated solution. 2. Usually we should think no extra bromide is necessary as pyro-metol works very cleanly with most plates, and tends to give very strong negatives. There may be some plates perhaps with which it is necessary. 3. You will want a wide-angle lens of about $f/16$ aperture. For a whole-plate the lens would be of from 6 to 7 inches focal length.
- C. B.—Certainly; these illuminating chambers act in the same way as a reflector in daylight enlarging, and tend to give softer results, although they are of benefit where a negative is heavily retouched. They are much slower than an enlarging condensing lantern, but we should doubt if they are slower than good daylight. At any rate, they handicap you considerably in dealing with dense negatives. The only enlarger on this system which we think is really thoroughly practical for professional purposes is the high-power reflector-enlarging chamber sold by Messrs. Marion's and fitted either with high-power half-watt lamps or arc lamps. The small illuminators with incandescent gas burners or comparatively low-power electric lamps are unsuited to professional work. We would sooner use a condenser lantern fitted with a "Howellite" incandescent gas burner or else with a "Luna" lamp of Messrs. W. C. Hughes burning methylated spirit. Even if you use a condenser, you can diffuse the light with ground glass when working from negatives with a lot of retouching on them.
- A. G.—1. If you cannot use either gas or electric light, the illuminating attachments sold for use in using an ordinary camera as an enlarger will not be very much good to you, because you will not be able to get oil lamps of sufficient power to use in it. Even if you can get incandescent gas burners or fairly high-power electric lamps, these illuminators are less efficient, particularly with negatives of rather great density, than the ordinary enlarger fitted with a condenser. 2. There is no fixed relation between the Watkins' speed figures and the H. and D. numbers, as marked by makers on plate boxes. You had far better stick to Watkins' numbers, which are reasonably correct. 3. Mercury vapour is a form of arc light, and requires electric current. 4. Distilled water is water made by condensing steam. By so doing all the solid impurities are left behind in the boiler. For photographic pur-

poses ordinary good tap water, if briskly boiled for a quarter of an hour and then allowed to cool without shaking about, is practically as good as distilled water.

N. E.—Considering that you have a pension of £3 weekly, which would go a good way towards covering household expenses, you should be able to start in a modest way with £100. Unfortunately, we believe it is the practice of the Government to pay only for actual purchases, and these must be estimated for in advance. In some cases we have known they have actually paid the bills direct, so that this precludes you from picking up the various items by advertising, by which you would probably save money. As regards outfit, we think you would do well to secure a whole-plate parallel bellows camera with a good $f/6$ lens. This would answer well for cabinet portraits indoors and also for outdoor work. You would require a studio stand and also a tripod for outdoor work. An enlarging lantern would also be desirable, since you would save much in comparison with putting this work out. The half-watt system is most economical for lighting. You would want at least three 1,000 c.p. lamps. These are better than one 3,000 c.p., as you will get diffused light without wasting light by thick diffusers which would be necessary with one lamp. Much depends upon whether you are handy with tools and can fit up your own backgrounds, reflectors, diffusers, and much of the dark-room fittings. From enquiries we have made we find that second-hand apparatus of good quality costs about full pre-war list prices. In the case of good lenses probably a little more. For example, a camera and lens of the quality you require would cost about £25, and another £5 would be necessary for the studio stand. The enlarger for half-plate negatives would cost at least £12. The half-watt lamps and switches, etc., about £10. Say £5 for backgrounds, another £5 for dishes, dark-room lamp, measures, stoneware sink, etc., and about £5 for a small supply of plates, paper, chemicals, mounts, etc. It is impossible for us to say what it would cost for blinds, decorations, and show-case, if needed, as prices vary and much depends upon the premises. Comparatively few things listed in pre-war catalogues are obtainable, and the prices prevailing are usually 75 per cent. to 100 per cent. up, so that it would be close work to cover these items with the balance of the £100.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)					

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

Application forms for particulars of postal address, etc., for insertion in the "B.J. Almanac," are now with firms in the trade.

The "Index to Goods Advertised" in the "Almanac" forms a buyers' guide of special appeal to the smaller advertiser.

The concluding instalment of the paper by Mr. Herbert G. Stokes deals with the design and use of a rotating and embossing board, and describes and illustrates the method of combining portraits from different negatives into the same print or enlargement. (P. 603.)

In his article this week "Practicus" deals with flashlight work of the kind which a photographer is called upon to undertake away from the studio. (P. 601.)

The exhibition of the Royal Photographic Society at 35, Russell Square, includes a somewhat small pictorial section and that, moreover, one in which landscape rather than portrait and figure work is predominant. A review of the portraiture, however, occupies the article on page 599. We shall supplement it next week by a personal impression of the exhibition, and particularly of the landscape work, by Mr. F. C. Tilney

We reprint this week the very excellent report (for the year 1918) by Mr. B. V. Storr of progress in photographic manufacturing and working processes and in the investigation of photography on the theoretical side. (P. 605.)

A method of producing lantern-slides in a series of warm tones is that originated some years ago by Dr. Traube. In a leading article we review some of the later developments which have been worked out particularly for cinema films, but equally applicable to lantern transparencies. (P. 598.)

The death is announced of Mr. Philip E. B. Jourdain, at one time a frequent contributor to our pages on the literature of photographic processes. (P. 610.)

Dr. J. M. Eder has completed a biography of the German doctor and scholar, Schulze, for whom the credit of the discovery of photography has long—and we think, quite unjustifiably—been claimed by German writers. (P. 598.)

It is reported that the making and distribution of cinema films for school and educational use are to be financed by the Hudson's Bay Company. (P. 597.)

The special merits of the portable diffusing screen in any arrangement of studio lighting are the subject of a paragraph on page 598.

Some useful mechanical hints were given in the course of a demonstration last week at the Croydon Camera Club. (P. 608.)

EX CATHEDRA.

The Trade Directory.

One feature in the "British Journal Almanac," as most photographers know, is a directory of the firms in the photographic and allied trades. Year by year this list of firms is brought up to date by revising the particulars of the postal and telegraphic addresses, and telephone numbers of each. Applications for these particulars have just been issued, and will, we hope, for the sake of avoiding unnecessary postal communications, be returned as speedily as possible. We are sometimes asked why we do not classify these firms under headings which will show the goods which they manufacture or supply. Such a scheme, however, deprives the directory of its simple alphabetical character, and in any case would lead to a good deal of duplication, even if a scheme of classification could be devised which would cover the entire production of the trade. Moreover, such an indication is given in the "Classified Index to Goods Advertised," which for some years past has also formed an important feature of the Almanac. In accordance with the scheme of its compilation, any firm inserting an advertisement (of however small a size) in the Almanac automatically figures in this Index under the heading or headings corresponding with the goods which are advertised. As may perhaps be emphasised with advantage, this is a feature of the Almanac which appeals particularly to the smaller advertiser, whose announcement obtains the same prominence in the Index as those of firms occupying much larger space. The fact deserves to be given prominence in the case of a volume in which advertisements large and small run altogether to many hundreds of pages.

* * *

School Cinema Films.

We have had to wait for a long time for the cinematograph to take the important place which it deserves as a medium of education, but it would seem that it is now shortly to arrive, and will do so along a most unexpected channel. According to a notice which appeared in the "Times" of Tuesday in last week, October 7, a union of three film-producing companies is to embark on the production and distribution of films for use in schools through the financial assistance of the Hudson's Bay Company. Those who have followed the history of this chartered "Company of Adventurers" from its establishment in the year 1670, and are aware of its great land-owning and trading interests in the Dominion of Canada would perhaps be the last to expect such a corporation to embark upon such a highly modern and specialised enterprise as cinematography. Yet Sir Robert Kindersley, Governor of the Company, and perhaps better known as the head of the War Savings organisation, is an astute financier who cannot have taken up this programme without reasonable assurance of its success. We learn that there are already in the United

States one thousand schools equipped with their own cinematograph apparatus, and that most of the schools now being built embody a film-projecting installation. The new company, which is to have a capital of £500,000, includes within itself experience in the making and distribution of short films in nearly a score of different countries. It is intended that at least four educational films will be produced every week for distribution throughout the world. Evidently, although it has been long in coming, teaching by cinematograph is to be organised on the most comprehensive scale.

* * *

Diffusing Screens.

We do not believe that the majority of portraitists properly appreciate the value of small translucent screens as a means of controlling the light falling upon the face. The lighting may be just what is required in all respects but one—that there is too much light upon the face. Any attempt to modify this with the blinds disturbs the scheme more or less, but if a small screen covered with thin muslin be interposed there will just be that toning down of the high-lights which gives the difference between flesh and chalk. A prevalent misconception is that the exposure is considerably increased by the use of such a screen, but upon making a trial it will be found that little, if any, additional exposure is needed to get the same degree of shadow detail, and this is quite what might be expected if we remember that the shadows are illuminated by reflected light, which is not reduced by the screen. If the light is softened at or near the glass, not only is the whole figure flattened, but the diffused light in the studio which illuminates the shadows is weakened as well. It may be well to give a word of caution against using too thick a material for the screen, and to see that it is kept reasonably clean.

* * *

Schulze and Wedgwood.

We see that Dr. J. M. Eder, of Vienna, has been occupying some of his leisure during the war most unprofitably in compiling a biography of the 18th century scholar, Hermann Schulze, of Halle, whom, for many years past, he has claimed to be the discoverer of photography. It remains to be seen whether the full text of this biographical memoir adds anything to the writings of Schulze which can be quoted in support of such a claim. Apparently, from a notice of the book which has been published in the Austrian journal "Photographische Korrespondenz," it does not bring any new facts to light. Therefore it may be worth while to recall once again what Schulze did. He was experimenting on the action of heat and light on various substances, and for this purpose had made a fluid mixture in a bottle chiefly of carbonate of lime, but containing also some silver compound. He found that the white mixture discoloured, and by fixing cut-out paper patterns to the outside of the bottle he was able to convince himself quite rightly that the discolouration was due to light. In hailing this observation of the 18th century—the date of it was 1727—as the discovery of photography Dr. Eder has persistently looked at it through the spectacles of the 19th century. Schulze's memoir, an excellent translation of which was published by the late Mr. Litchfield in his book, "Tom Wedgwood: The First Photographer," comments upon the curious effect of the paper patterns being transiently copied upon his fluid mixture, but there is nothing in it to suggest that he perceived in the experiment the germ of a method of copying stencil patterns or anything else. It is plain that he was concerned with finding out by this means that the light affected his mixture. This observation having been made, he gives the bottle a shake and the patterns vanish. In interpreting Schulze's observation as the discovery of photography—a German

discovery—Dr. Eder has allowed himself to be drawn from his customary habit of impartial historical judgment. If any one man can be credited with the idea of employing the action of light for representing the forms of objects and at the same time with the description of some process for carrying it out, that man is Tom Wedgwood, the third son of the famous potter. We see that Dr. Eder in his biography of Schulze is dealing with what literature has gathered around his subject. It may be hoped that he will be able to discuss the criticism of Schulze's claims contained in Litchfield's biography of Wedgwood.

METHODS FOR THE DYE-TONING OF LANTERN SLIDES.

FORTUNATELY within the last ten years or so there has been the most marked improvement in the quality of slides used by lantern lecturers, who are themselves photographers. The old standards have passed away, and the lantern lecturer of to-day is expected to compete in a measure with the makers of prints for the exhibitions. Perhaps this higher standard of quality has come about from the exceedingly fine work of a very small circle of lantern-slide makers, among whom may be mentioned particularly Mr. Fredk. H. Evans, Mr. James Shaw, and Mr. J. Dudley Johnston. The last-named, it will be remembered, discoursed a year or so ago on the pains which he is accustomed to take to secure a certain character throughout a whole lecture set of slides, and to depart from it in the deliberate intention of producing a carefully considered degree of variety. Mr. Johnston obtains his effect by direct development, and probably if other slide-makers of equal eminence were canvassed it would be found that they also prefer this method to the many processes of after-toning, which at one time or another have come into use. Certainly the methods of producing warm tones by toning with uranium or copper have declined enormously in popularity owing to the lack of transparency which the results exhibit. Other methods, which are less open to this objection, have never come into anything like general employment, although there is much to be said for the effects obtained by the simple process of converting the black-and-white slide into an image of silver chloride, bromide, or iodide, which was worked out by the late Welborne Piper.

There is, however, another class of toning process which is coming largely into use for cinematograph film, and is equally applicable to the transparencies of the lantern-slide maker. This is the process of dye-toning, which consists in bleaching the black silver image, thereby converting it into a compound, which can mordant or "take" dye from a bath in which the bleached slides are allowed to soak. The original process of this kind was devised some eight or nine years ago by Dr. Traube, and known as "Diachrome." The ordinary lantern-slide is bleached by means of a solution of iodine to yield an image consisting of silver iodide. The silver iodide acts as a mordant towards a large number of dyes, the dye becoming more or less firmly fixed upon the silver iodide. Slides treated simply according to the process in this form show extremely pleasant tones on the projection screen. In carrying out the process no notice must be taken of the appearance of the slide, for one which is a bright red when viewed by reflected light will show on the screen as a cool brown, and the difference is just as great in the use of other dye baths. While a slide requires to be projected in order to find out what is the effect of the process, the method is extremely regular in working, and once a given bath of dye has been selected

the effect on the screen will be the same with any number of slides which are passed through it.

The presence of the iodide of silver in the image gives a softening effect, while it also adds to the opacity of the emulsion. Such slides are not very suitable for exhibition by means of a light of moderate power, but show excellently with the arc or oxy-hydrogen light. The silver iodide can, however, be removed by means of a strong solution of hypo, and if the slide has previously been passed through a hardening bath of tannin or formaline the image will be left consisting almost completely of the dye, which was attached in the first instance to the silver iodide. These dye-transparencies yield effects on the screen very different from those from transparencies containing the silver iodide. The colours are of exceptional brilliancy and purity—in fact, much too vivid and brilliant for the purposes of a lantern lecture. If used in any variety an audience is soon wearied by them, whilst the repetition of one colour becomes conspicuously monotonous. Our own feeling is that for the lantern lecturer the simpler process, in which the silver haloid is retained in the image, is much the more valuable, and is indeed one which deserves to be much more widely used than it has been. We venture to think that makers of lantern slides will find in this process, or rather in the further developments of it which we shall now pass to mention, an interesting and profitable field for experiment during the winter season which is now opening.

One of the first modifications in the Traube process was that which was the subject of a patent by the Brewster Film Corporation, whose specification was published in the "B. J." of June 8, 1917, p. 303. According to this specification the silver image may be treated in the first instance in an iodine bath, which gives a silver-iodide image of much greater transparency. The formula recommended was:—Potassium iodide, 50 gms.; iodine, 1.5 gms.; 3 per cent. solution of glacial acetic acid, 50 c.c.s.; water to make 1,000 c.c.s. Apparently, the chief difference between this bath and that of Traube lies in the much larger proportion of iodide. The same principle

is adopted in compounding the bath simply from iodide, acetic acid, and bichromate, according to the formula:—Potassium iodide, 50 gms.; 3 per cent. solution of glacial acetic acid, 50 to 250 c.c.s.; 1 per cent. solution of potassium bichromate, 50 to 250 c.c.s.; water to make 1,000 c.c.s.

The process has latterly been given a different form by the two American workers, Mr. F. E. Ives and Mr. J. I. Crabtree, of the Eastman Research Laboratory, the latter of whom was the first to publish working details. It was found that the iodine can be replaced by the much cheaper bleach of copper ferricyanide (similar to the ordinary copper-toning formula of Ferguson), which gives an image of copper ferrocyanide, capable of fixing the dye in the same way that silver iodide does. The practical instructions in this process were published in the "B.J." of August 9, 1918, p. 357. Mr. Ives has subsequently worked out still another bleach yielding an image which mordants a dye. This is a solution of equal parts of potassium ferricyanide and chromic acid, the action of which can be to produce a bleached image of a high degree of transparency. A suitable bleaching bath consists of 1 oz. each of potassium ferricyanide and chromic acid dissolved in 120 ozs. of water. After bleaching, the yellow stain of the chromic acid is removed in a bath containing a little soda bicarbonate, and the remainder of the process then consists simply in soaking the slides in a bath of dye acidulated with acetic acid and in washing out excess of dye in water, likewise rendered very slightly acid with acetic acid. Considering that a considerable variety of dyes are available for these processes and the very occasional exposure to light which the toned slides receive, there is no reason for disparagement of the process on the ground of fugitiveness of the results. From the references which we have given those interested in it should find ample guidance for their experiments, and may be encouraged to extend the field of work in the direction of discovering still other bleaching solutions which may be employed to produce fixatives of dyes.

THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

Portraits and Figure Studies.

THE sensations in this exhibition do not lie among the portraits. There are but a hundred and twenty-four prints in the Meeting Room at 35 Russell Square, and that room constitutes the chief and largest gallery, filled with some excellent landscape work and a remarkably small proportion of portraits proper.

In our review of the London Salon we remarked upon the fact that the best of the portraiture there came from overseas. In Russell Square the examples are all of native origin. We are therefore able to get a truer idea of the British harvest than we could at Pall Mall, and on the whole we are disposed to think that the home production remains, by comparison, feeble, even when taking into account the fact that many of our best professional workers do not show here. The amateur does his best to support the nation's reputation.

The first print is "A Study in Expression" (1), by H. Lamplough jun. As we happen to know, Mr. Lamplough is quite young, and if the visitor could discount the "make-up" and the expression of the Italian-looking head before him, which is thrown back in laughter, some idea of the photographer's own physiognomy might be gleaned; for effective

and convincing as is this study, it is, we understand, a self-portrait. The attempt shows enterprise and resource, and in that respect is welcome at a time when almost every aspect of a portrait but the expression seems to occupy the attention of the photographic community.

Miss Marjorie Cooke's "Portrait" (2) has claims to character rather than expression. It is simple and good in style, entirely free from any show-case attractiveness, but satisfying to the last degree. "85° F. in the Shade" (3), by Andrew Barclay, is a distinct bid, however, for the kind of approval that our "knuts" bestow on the pictures of hand-painted stockinged damsels in Burlington Arcade. It would be *risqué* but it isn't. We assume that those grave and reverend signiors who selected this innocuous naughtiness for exhibition imagined they were putting a plum into the pie of the R.P.S. We much prefer Mr. Barclay's "Plumes" (6), theatrical in subject and treatment though it be. "The Black Bonnet" (120) reminds us of the photographs of actresses which used to adorn the illustrated weeklies of a quarter of a century ago. It is very harsh in its light and shade. "Alluring" (122), on the contrary, is as flat as it could be. It represents a lady at full face with an expression

of masterfulness which only the inexperienced bachelor could deem alluring. All these works are good in their way; but it is a photographic and worldly way. The artistic charms of happy design, of effective lighting, and of quality have not proved so alluring as mere personality. Carelessness in composition may be overcome, but banality in effect and lack of quality are almost inevitable with the artificial lighting that Mr. Barclay pins his faith to. As a contrast we may turn to Mrs. Ambrose Ralli's splendidly strong example of character work called "A Sussex Type" (10). Here the light and shade is crisp and searching, and produces an effect wonderfully similar to that which distinguished the work of D. O. Hill. The face of this old man is a triumph of delineation. We could have wished, however, that Mrs. Ralli had trimmed off as much as possible of the near coat sleeve, which is exaggerated in size to the detriment of a fine picture. The comparison of these two methods of work certainly raises the question as to how far the conveniences of artificial lighting are a compensation for the loss of the natural and virile lighting of earlier methods. It is pretty certain that the masculine and forceful delineation which bright daylight, or even direct sunlight on occasion, can bring about, will exert a fascination for the public as soon as they are tired of the generalised and sweetened effects which artificial lighting seems to make for, and that period cannot be long in coming. Attempts are made, of course, to simulate the natural strength of presentment, but laudable though they be, they are still obviously not the real thing. It would seem to be artistic wisdom, at any rate, to preserve in the studio a few facilities for natural lighting, as a safeguard against an inevitable mannerism which the exclusive instalment of lighting plant must involve.

It is surprising, indeed, that the intrinsic beauties of light and shade are so rarely studied, even by the amateur who makes the quest of art his claim for using the camera. For example, Robert Chalmers's "Esmeralda" (4) is a head and shoulders with a fine sense of style, but is typical of that photographic custom of bathing a whole subject in a sort of brown sauce which robs it of all freshness and sparkle. No one denies the rather luxurious quality of this sauce at times, and particularly in this example, but it is not always enjoyable in this way. Often it is mere flatness and darkness. "The Model" (9), by Charles Borup, is what one might call "sodden" with this degradation of tone so discounting to the merits of the work. The Earl of Carnarvon shows two prints of much charm as far as their subject-matter is concerned. "Fur Cap" (7) is one of the darkest prints in portraiture that we have ever seen. It cannot be denied that modelling is here in abundance; but all the same a spectator would hardly take the trouble to follow it out did not the beauty of the face tempt and reward him in the process. We do not in actual life see things in this way as a general rule. It would be in extremely privileged and intimate circumstances that we should be permitted to examine a young lady's modelling as we may with impunity examine the modelling of "Fur Cap." "The Bird" (11) is another example almost as unreasonable. The bird is a trifling detail of taxidermy just discernible upon the lady's finger, who, herself, is really the proper claimant to the title. But the point is that her face is lit from below—a ruse that can scarcely boast the exhilaration of novelty. The lighting, however, is whispered, if one might borrow a term from another of the five senses. It is so faint that it leaves no doubt of its distant and feeble source. A lighted match would make a far more powerful display. The logical mind can only assume that this lady elected to stand almost in the pitch dark and play with a stuffed bird upon her finger. Does such an inevitable assumption increase the attractiveness of the print? Even that artistic Cardiff photographer, Hugo van Wadenoyen, jun., does not avoid the incubus of gloom in his "Portrait of a Man" (115).

This kind of work always has, and apparently always will be the dead weight on real artistic progress. There is no reason why it should exist at all. It is just as easy to make bright and lively prints as it is to produce this sodden kind of quality. A few professionals have shaken themselves free of it, but many still remain under the domination of the amateur in this respect. The amateur's part is to be artistic, of course, but too many of them postulate that the artistic is necessarily not the commonplace, and that they therefore avoid it at all costs. But the sun is the greatest commonplace in the universe and the shadows he causes are a counterpart of his glorious revelation of form which does not take place without them. It is an ingenuous recognition of this fact that photography is in need of to reanimate it. There is in light and shade provision for all the beauties of representation short of colour; and light and shade must be accepted as they appear to the eye and the mind. They must not be subdued and "treated" until they pass beyond that point of commonplace which our experience recognises.

"Miss Queenie Thomas," in her leopard skin, by Angus Basil, shows dramatic force of design. His two nudes point to the emancipation of the public in general, and of photographers in particular. One, "Reflections" (34), however, does not seem to serve any important artistic purpose; but "Bullrushes" (37) is a well-schemed picture of a lady—or a nymph—by a stream which reflects the trees above in a happily pictorial manner.

The "Portrait Study of the Prime Minister" (12), by Miss Olive Edis, is scarcely the *pièce de résistance* of the show that it might have been. The vertical division of the face between light and shade is not quite happy. However, the portrait gives in a very life-like way the twinkle in the eyes which is the Premier's never-failing popular grace. We welcome in Mrs. Barton's "Fair Rosamund" (28) a return from her flat method to a naturalistic roundness, and think that in this respect the R.P.S. has secured her best effort. Nevertheless, we do not care for the sloping lines of the composition. Nor can we congratulate the R.P.S. upon two specimens of work sent by Chas. H. Davis from New Jersey. Both his head "Studies" (27 and 29) are commonplaces of art—not of nature. But Mr. Davis retrieves his reputation in "Mirror Portrait" (38), in which a pretty sitter looks into a cheval glass in turning her back upon us, whilst we see her full face in perfect delineation reflected. It is a nice idea, not new by any means, but managed with more success than is usual. As a photograph, Robert Chalmers's costume study, "The Snuff Box" (31), leaves little to be desired; but he should have prevented his sitter from assuming the facial expression of a music-hall singer.

One of the most important portraits in the show, at any rate as regards size, is "W. B. Ferguson, K.C., etc." (92). This is by that skilful worker, N. E. Luboshez, who carried off the palm here last year. His present contribution is not so striking a work as those of 1918, chiefly because his scheme of lighting is ineffective. But the genial Vice-President, in wig and gown, is presented with character, and the treatment is manly and straightforward, devoid of all attempts at adventurous artistry. "Beatrice Essenhigh Corke" (94) is a very charming work by Charles Borup, posed with much grace. There is grace, too, in the two heads, presumably a mother and son, of "The Kiss" (93). This is by Martin R. Tozer, who somehow has failed to endue the print with the strength it required.

We confess to liking the treatment of the head of "Hugo Van Wadenoyen, Junr., F.R.P.S." (117), about as well as anything here. It is extremely strong in presentment, yet full of nuance: its lighting highly effective and its characterisation interesting. It is a conquest for its author, M. R. Leeming.

The management of the backgrounds in F. Spalding, Junr.'s "Portrait, Miss S." (119), and in "The Smith" (116), by Geo. Spiers, is in neither case satisfactory. It is surely not advis-

able to put demonstrative features where they may interfere with the accents of tone in the subject. A modified background is desirable, of course, but it should not be modified into aggressiveness. Stephen W. Shore does not do himself justice in "Little Mary" (118). It is rather tame and characterless for him, who usually produces portraits of strength and meaning. C. P. Crowther had better opportunities in the smart and dashing soldier, "Un Diable Noir" (121). Here is characterisation in abundance: a fine swinging pose, well fitted to the picturesque uniform, and a handsome sitter, to whose gentlemanly bearing has been added the merest touch of the swashbuckler. Mr. Crowther also sends two of his excellent Japanese play characters, "Akogi" (the Ghost of a Fisherman) (36) and "Shakkyo" (the Spirit of a Lion) (40). Besides being remarkably fine prints, these things are intensely interesting in themselves. The masks the figures wear are wonderfully designed. In the first there is the general haggard or shrunken look of a corpse that is on the way to being a skeleton. In the other the jaws suggest the narrow but deep cavity of the lion's gaping mouth; but it is less realism than fine decorative design. "C. P. Crowther, Esq." (123), himself is the subject of an excellent print by Messrs. Millar and Scott, who also send "The Rt. Hon. the Earl of Carnarvon" (124) in a particularly free-and-easy attitude, with soft hat, very much "squashed," and a cigarette. The last print in the room is Hugo van Wadenoyen, Junr.'s "Mr. Henry Ainley" (124a). This seems to us too large in scale and too hard in treatment to be pleasing. The light on the forehead is more like sunshine on a granite rock than a gleam upon flesh.

Figure studies that are not portraiture do not amount to much. The most pictorial are Miss Kate Smith's two outdoor figure pictures, "The Ball" (35), a diaphanously-robed nude skipping along as she tosses up a ball—technically a fine achievement; and "Arcadian Angler" (41), a pretty figure bending over the edge of a stream, and charmingly lit by gentle light from overhead. "Light and Learning" (16)

is the only real sunlight portrait-study here. It represents a youngster sitting in the hall of a house with a book. The open doorway sheds a flood of sunshine upon him, and the arch of the portal forms a kind of canopy of shade on the wall behind him, and so makes some sort of a design giving the work a distinctive character. "Romany Chals" (18) will appeal to lovers of Borrow. It is a group of seated gipsies—surely a new variety of sitter. Its author, Richard Hopkins, should follow the best-looking one up for a fancy portrait of Isopel. We cannot exactly find the plurality of figures in "The Fishermen" (23), by Mr. and Mrs. F. Weston, but there is a single figure, a back view of a nude standing in the marge of the sea, and this is an excellent study, anatomically and photographically. Another nude, a young boy this time, is sent by Mrs. Maud Basil, called "Is My Parting Straight?" (37). He stands in his bedroom before his dressing-table and exhibits this concern about his hair before he has a stitch of clothing on. The print has nice quality.

Visitors will further be interested in a remarkable series of photographs taken in the South Pacific Islands by Thomas J. McMahon, F.R.G.S. They deal with the life and customs of the inhabitants that Stevenson knew. Some of the types are remarkably fine specimens of humanity, the ladies being by no means unpleasant to look upon. The ceremonial adornment of the naked males is amazing, especially when compared with a native king in full panoply of top-hat, frock-coat, and everything else of modern costume in the style of Balham at its best.

Colour transparencies are no worse than they have ever been, but there is one that deserves special mention because it is perhaps the best that ever has been in portraiture by this process. It is the production of Lucien Talamon, "Portrait de Mlle. N." (169), and it is medalled. Finer grace and better modelling one could not hope for, and the colour of the head-dress is a triumph.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).

Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).
 Miniatures (Sept. 19).
 Printing Portrait Negatives (Sept. 26).
 Wedding Groups (Oct. 3).
 Combination Printing (Oct. 10).

FLASHLIGHT WORK.

MANY people attempt flash-light photography, yet very few seem to get even passable results, and, after looking at the earliest published book on the subject, that written by Robert Slingsby, about a quarter of a century ago, I feel that although

considerable improvements in materials and apparatus have been made, we can show little, if any, progress in the actual photographic work. This is probably due to the fact that those photographers whose knowledge of the principles of lighting

would enable them to use the flash intelligently, do not recognise its powers, while many others who work, as one may say, blindfold, turn out the astonishingly poor work which brings discredit on the system.

The first thing which has to be realised is that flash-light is no different from any source of illumination emanating from a small area, and that practically the same effects can be produced with it as can be obtained with an enclosed arc, half-watt lamp, or even a small window, placed in the *same relative position with regard to the sitter*. Similarly, if we consider an un-screened flash as direct sunlight, we have advanced another step towards obtaining satisfactory portraits. Another important point is that the flash resembles the electric light, inasmuch as the source of illumination is comparatively near the sitter, and not at a distance of many millions of miles, as is the sun. If these elementary principles are borne in mind, the flash-light problem is much simplified. Let us now endeavour to apply them in the production of an ordinary "three-quarter light" portrait of a single figure.

Taking the first point, we find that we have to place the light high enough to give proper relief to the features, and to avoid suffusing the eyes with light. As a general rule, the light should be the same distance above the head of the sitter as it is away from him in the horizontal line—that is to say, if the stand supporting the lamp is three feet away from the sitter's head, it should be three feet above it, and so on with all other distances. This gives the orthodox light angle of 45 deg., which is what we require for this class of lighting. Excess of both front and side lighting must be avoided by placing the flash-lamp towards one side of the head, and not directly over the lens.

Next, we find that the un-screened flash gives what the daylight photographer calls "overlighting." Therefore we must interpose a diffusing screen, and, lastly, we must remember that, roughly speaking, the intensity of the light varies in inverse ratio to the square of the distance between it and the sitter, so that to avoid an excessive consumption of powder we must not make this distance too great. As in a properly arranged flash, the light produced is in direct proportion to the weight of powder burned, we see that if 50 grains of powder are sufficient to give the desired exposure at three feet distance, we must use 200 grains to get the same effect at six feet. This can easily be seen in any flash-light dinner picture wherein the distant faces are nearly black from under-exposure, while the nearest ones are more or less over-exposed.

There have been many methods of producing the flash, the oldest and safest being by igniting pure powdered magnesium by blowing it through a spirit or gas flame, and the more modern and most generally used being the firing of an explosive compound which contains magnesium by means of touch paper, some form of detonator, or an electric spark. Another way of firing is by means of a spring-driven wheel and flint similar to those fitted in the ordinary petrol lighters used by smokers.

The use of pure magnesium has almost died out, and nearly all photographers use one or other of the explosive mixtures

now upon the market. Many formulæ for making these have appeared from time to time, but as I strongly deprecate their manufacture at home, I shall not give any, as I consider it as safer and more satisfactory to use one of the ready-made powders. Mixed flash powders must be treated with the greatest care, as the majority of them are more violently explosive than gunpowder, and not only severe burning of the person, but destruction of the premises, may result from incautious use. On no account may these powders be used in any form of lamp with a closed chamber, but they must always be fired in an open tray.

I have tried many forms of flash-lamps, and some of them are very good, when they work, but, unfortunately, I have never found a thoroughly reliable one yet, and there is nothing so annoying as to attempt to make an exposure on a group, and fail. I have therefore practically abandoned all mechanical or electrical contrivances, and adopted the primitive method of using touch paper, and as I always light two slips at once, I am never in doubt about the flash. My lamp is made of a sheet of tin about 15 inches square; this is bent so as to form a shallow tray about four inches wide and fifteen long, with a half-inch rim turned up all round. The remainder of the tin serves as a reflector, and has a tin loop riveted to the back, to take the end of a stout bamboo or wooden rod. This rod should be jointed, as for large groups it is often necessary to fire the flash nine to ten feet from the floor.

The method of working is, perhaps, best described by giving particulars of an actual exposure. The subject was a machine at which some engineers were working in a dark basement. The lens, a $f/4.5$ homocentric, about 7 in. focal length, working at $f/16$ for $6\frac{1}{2}$ by $4\frac{3}{4}$; flash powder, Johnson's; plate, well, there are plenty of good plates to choose from. I used one marked 275 H. and D., and it was backed. After focussing and placing the slide in the camera, I took a good teaspoonful of the powder and spread it in a long ridge along the tray. Into this ridge in two places I tucked strips of *well-dried* touch-paper, bent into a gutter shape, each with one end standing about an inch clear from the powder. The next thing was to draw the slide, uncap the lens, and apply a match to the touch paper. As soon as this was well alight the lamp was raised to a height of about seven feet, and in a few seconds the flash occurred. The lens was covered at once, and all was ready for the next subject. The negative was developed in a solution of half normal strength, to secure softness, as there is always a tendency to undue contrasts when the flash is used without a screen, which is practically always the case except in portraiture. Ample ventilation should be provided, so that the smoke from the flash will clear away quickly. The stock tin of flash powder must be covered before firing the flash, or a spark may explode the lot. More than one fatal accident has occurred in America through neglect of this precaution. There is much more to be said about flash-light, but I have reached my allotted space for this week. Studio work will be dealt with in another article.

PRACTICUS.

FORTHCOMING EXHIBITIONS.

October 13 to November 29.—Royal Photographic Society.—Secretary, J. McIntosh, 35, Russell Square, W.C.1.

November 12 to 15.—Rotherham Photographic Society. Entries close November 3. Hon. Sec., C. Robinson, 26, Broom Grove, Rotherham

November 20 to 22.—Nottingham and Notts. Photographic Society. Entries close November 8. Hon. Sec., A. Beeston, 103, Nottingham Road, Nottingham.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Entries close December 1. Sec.: John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The directors of the Eastman Kodak Company of New Jersey have declared an extra dividend of 2½ per cent. upon the common stock, payable on December 1 to stockholders on record at the close of business on October 31.

FINE CHEMICALS.—Those who have occasion to require pure chemical substances for experimental purposes, and may previously have regarded the German firms supplying these products as exceptional sources, should make a note of the price list now issued at frequent intervals by the British Drug Houses, Limited, 22-30, Graham Street, City Road, London, N.1. It is a most comprehensive list of organic and inorganic chemicals, of microscopic stains, aniline dyes, as well as of the photographic chemicals in common use.

EFFICIENCY IN THE WORKROOM.

(Continued from page 590.)

Fig. 12 shows embossing board with registration guide at left hand corner. Near the centre is a bevelled opening. The cards used for embossing are glued to a wooden block which is also bevelled so that it will more easily fit into the opening of the baseboard. The advantage of the opening and blocks is to overcome the need of separate and entire apparatus for each

Fig. 12.—Embossing board fitted with registration guide.

different border to be embossed. The registration guide is glued permanently to the board, and all that is necessary to meet the requirements of various embossing measurements is just the addition of blocks and the different size embossing boards. Prints that have no tinted border could also be embossed by this device, provided the simple registration scheme is followed in the printing. Since preparing this embosser I have enlarged and perfected the idea by adding a rotary base board with embosser complete.

The embossing of prints is a process that many studios omit, owing to uncertain results and the length of time necessary to obtain fine accuracy. This embosser fills a need, long felt by most studios for an embossing device that will cut down time and give an accurate result. It reduces the process to a mechanical basis, saves two-thirds of the time on the old method, and makes it possible for every studio to deliver its artist proof and other style prints with a neat, accurate embossed line, which always add to the attractiveness of a picture. It is so simple in its operation that any member of the studio help can handle it without fear of spoilt prints and imperfect results, and the rotary base board enables one to remain in one position during the embossing of the four sides of the print.

Fig. 13 shows the method of changing embossing boards which accommodates the various size embossing measurements. I have

Fig. 13.—Embossing board, showing embossing block being changed.

given this apparatus exhaustive tests, and have proved beyond a doubt that for speed, accuracy, and general efficiency it is thoroughly practical.

Fig. 14 shows the operation of embossing, and Fig. 15 the method of rotating base board. It really makes embossing so simple that a child could almost handle it, because it reduces

the process to a purely mechanical basis. Great care is necessary in the initial work of cutting and preparing the embossing boards, and gluing them to the bevelled blocks. One-sixteenth

Fig. 14.—Embossing the print.

of an inch makes all the difference between perfect and imperfect embossing. But once this board is fastened to the bevelled block the rest is easy. I have found that to have this embossing

Fig. 15.—Turning the baseboard.

apparatus made by a cabinet maker was too expensive for most photographers, and those who are sufficiently interested are probably aware that this apparatus is now on the market and can be obtained through any photographic dealer.

Fig. 16.—Press for flattening prints.

The press illustrated in Fig. 16 is for flattening prints of all sizes. No doubt many studios possess a similar one, and probably there are better methods of performing this necessary process; but I have found this a useful piece of workroom

accessory. It is built entirely of wood, with a base inside measurements 20 x 24, four uprights of substantial thickness, and two cross-pieces at the top. In the centre is a large wooden screw which is securely fastened to a piece of wood the same measurement and thickness as inside of base. Sixteen-ply card and blotters are interposed between the prints, and a press this size has a capacity of about 200 11 x 14, 500 8 x 10, or 1,000 5 x 7 prints. Pressure for about two hours is sufficient to insure perfectly flat prints. This press would be of no use to studios where the method of drying and flattening is performed under one process. But for those who prefer backing the prints with a weak solution of gelatine, or for studios where flattening of prints is a separate process, it will be found very handy, and it has the advantage of occupying very little space.

My final point for illustration is one that will probably interest the majority of photographers. It is a plan for saving imperfect group pictures when a re-sitting is either impossible or difficult to get. Many a pretty group has been rejected because one figure in it has either moved or wears an expression that resembles a Bolshevik outburst. Many a good order has been lost through the same cause. Briefly, my scheme is the combination of two imperfect negatives to make one perfect picture. Many articles have been published showing how this can be done through the medium of printing-out papers.

To those of you who have passed through the old daylight printing days this plan will perhaps be a familiar one. Mine is just a revival of the principle of combining two prints in one by daylight printing, using transmitted light for registration, and applying this principle to present day developing printing methods. So please bear in mind it is not the discovery of this principle, but only its application, of which I am going to speak.

Figs. 17 and 18 show the two negatives from which it is proposed to make the final print. The rendering of the two boys is

Fig. 17.

Fig. 18.

The figures of the two boys in Fig. 17 are to be combined with that of the girl in Fig. 18.

acceptable, but the little girl in the window seat, having moved, the effect as a whole is spoiled. In the other negative we have a good picture of the girl, whilst the other subjects are not so pleasing. Now, by taking the little girl from negative No. 18 and inserting her in No. 17, we get a picture which will entirely satisfy our client.

To do this, first examine negative to see the section best suited for cutting out part to be transferred, so that if a slightly imperfect registration takes place it can easily be disguised by spotting. The folds of a curtain or dress, the edge of a picture frame are outlines to be chosen when cutting. All these points will become apparent after a very little practice.

In the instance illustrated I cut through the folds of the drapery, along the outline of the little girl's leg and foot, and through the corner of room to floor. Having cut around section to be transferred I glue this section on the glass side of the negative, blocking out everything except the part to be printed.

On the glass side of other negative is glued the other section. Figs. 19 and 20 will show more clearly what I mean.

Let me explain here why it is necessary for these operations to be performed on the back of negative. The thickness of the glass allows just the correct amount of softness along the edges

Fig. 19.

Fig. 20.

Part of the subject is blocked out from fig. 17. Result is fig. 19. That from fig. 18 is fig. 20.

of transfer, which, if worked from front of negative, would give us a sharp, decided outline, and also make the registration a much more exacting process.

Having arrived at this stage, we make a print first from the negative showing most of picture. The reason for this will be obvious after a little practice. Before making the exposure hold the paper in contact with the negative, and by the aid of the transmitted light of the printing machine draw a pencil

Fig. 21.—Result of combination printing from negatives of figs. 19 and 20.

line around the outline of the section to be transferred. Make the exposure of this section, then place the other negative in position, and by transmitted light register the pencilled outline with the outline of this section. Expose this, and regulate the exposure according to the relative densities of the two negatives.

The print is now ready for developing, and if ordinary care

has been taken the result should be a perfect picture from two imperfect negatives. All these elaborate and detailed explanations make this process appear one of extraordinary difficulty, but it is surprisingly simple and easy after a few attempts.

Fig. 21 is the result of these operations, and although this

picture was cut and joined from top to bottom, not a particle of spotting has been employed to hide the join; proving that it is not necessary to keep an airbrush or expert artist to camouflage imperfect printing.

HERBERT G. STOKES.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[In January last we reprinted the second annual report on progress of photographic manufacture compiled by Mr. B. V. Storr, M.Sc., of the Ilford Company, for the Society of Chemical Industry. This report concerned itself with items of progress which had obtained publication during the year 1917. The fact of its delayed appearance was not to be laid to the charge of Mr. Storr, since the report appeared with a score of others on different branches of technology in a single volume, and the publication of the whole was, therefore, dependent upon the receipt of "copy" from the latest of the reporters. In now publishing the report for the year 1918 we must correct the impression that there has been further considerable delay on the part of the Society of Chemical Industry. As a matter of fact, the volume of those reports for 1918 was published as long ago as March last, but escaped our attention owing to its having appeared so soon after that of the preceding year. As we would not forgo the opportunity of recording in our pages the excellent digest of many items of photographic technology which are compressed within Mr. Storr's report it is right that we should make this acknowledgment as to date both to him and to the Society of Chemical Industry. The latter, we now learn, have made arrangements whereby these annual reports will be issued immediately after the end of the year with which they deal.—EDS., "B. J."]

THE most serious of the difficulties with which photographic manufacturers in this country have had to contend during the past year has been the shortage of glass, which became so acute as to necessitate not only the still greater use of old negative glass, but the making of an arrangement by which the acceptance of an order is conditional on a supply by the customer of a proportional amount of glass. The value of such glass is much less than that of new glass, partly on account of mechanical defects, such as scratches, but more because of the difficulty of removing all stains, opalescence, etc., produced by the previous treatment. The solution of this problem has not been published, but an idea of the difficulties is given by Waggoner,¹ who found it impossible to make such glass fit for silvering either by the use of strong chemicals or even by heating to softening point. His explanation of a mechanical etching of the surface, less where the silver image reduces the intimacy of contact, will hardly cover all cases in which the surface of glass is affected as regards coating with a sensitive emulsion, and it is more probable that the porosity of the glass, as suggested by Rheinberg, is the cause of the trouble.

The supply of good photographic raw paper, in common with all papers, has been restricted, although several British firms are making excellent base. Baryta coating is being successfully done by several British firms who specialise in this, and also by several photographic paper manufacturers, amongst whom the practice of doing their own baryta-coating is becoming more common.

Suitable packing papers, both for plates and for sensitised paper, have been increasingly difficult to get. Straw-paper especially, which has been extensively used for the packing of print-out-papers, has been almost off the market, and there does not appear as yet to be an appreciable quantity made in this country.

The supply of good quality photographic gelatine, both British and French, has also been short, the difficulties here being due to poor raw material, combined, in the case of those firms who have only lately taken up the manufacture, with a lack of experience, a matter in which the photographic manufacturer can give only very limited assistance (see later). It would appear, however, that with improved raw material British firms should be able to cope with British requirements both in quality and in quantity.

So far as chemicals are concerned there has been little in the way of actual shortage, although prices have been maintained at a high level. Silver, for instance, has risen from about 3s. 9d. per oz. at the beginning of the year to about 4s. 4d. The price of bromides has fluctuated considerably, and the absence of shipping facilities produced for a time a distinct shortage. A small amount of British-made bromide, presumably from American or French bromine, has been on the market, but the bulk of it has come from America. On the whole the quality has been well maintained, although somewhat greater care has been necessary in testing, and the proportion of chloride present has shown considerable variation.

The total effect of such conditions to the customer, apart from

shortage owing to priority of war contracts, has been a considerable increase of price and uncertainty of supply, but with little if any reduction in quality.

The supply of subsidiary chemicals such as developing agents, sulphite, alkalis, and thiosulphate, has also been maintained, although in some cases at very enhanced prices. All the more important commonly used developers are now made in this country, and can be obtained in a satisfactory condition as regards purity. The conditions in America have been as stringent as here, and to judge from the results obtained by H. T. Clarke,² adulteration has been fairly common; he gives examples of analyses showing misnaming and considerable adulteration and a list of twenty-five adulterants found in various developers actually on sale.

The production of photographic dyes, more particularly of colour sensitizers, in this country is now well established. The value of this to the Royal Air Force, who used large numbers of panchromatic plates and of colour filters in their observational work, can hardly be overestimated. The range of dyes for purposes such as anti-halation plates, tinting, the making of colour filters and safelights, etc., is, however, still very limited, and it is to be hoped that this will soon be put on to a footing comparable with the lists issued by one or two German firms.

The general question of economy in photographic processes is one which probably needs greater consideration than it has hitherto obtained. The chief sources of waste are glass, paper, silver bromide, and nitrates. The greater part of the waste glass is washed, broken up, and returned to the glass manufacturers. A fair proportion of the waste silver is collected and sent to the refiners for recovery, but there is probably a serious source of waste in very dilute emulsions occurring in certain processes, in which the proportion of silver is so small that it cannot economically be recovered by the usual means. The value of the process of Ilford, Limited (Annual Reports, 2, 505) for the treatment of such emulsions has now been thoroughly tested and proved. A process has also been introduced in Germany³ for treatment by metal precipitation, the metal being in the form of balls or rollers maintained in continual motion as the liquid passes through. The ordinary recovery processes also take account only of the silver and not of the bromine generally combined with it; at the present prices of bromine this should certainly be worth recovery. The gross value of the waste nitrates, the bulk of it either the potassium or ammonium salt, is also very appreciable, but its recovery is a more difficult problem because of the great dilution of the solutions; some biological method for utilisation of the nitrogen might be possible, although even that might be interfered with by the small quantity of bromide which is present with the nitrates.

The greatest source of waste, however, and that for which, as far as the writer is aware, no recovery process is in use, is probably the photographic paper—trimmings, etc.; the greater part is con-

¹ Communication from Eastman Kodak Research Laboratory *Brit. J. Phot.*, 1918, (65), 493; *J.*, 1918, 184.

² Ger. Pat. 302279; *J.*, 1918, 379.

³ *Phys. Rev.*, 1918, (11), 137; *Sci. Abs.*, 1918, (21), 206.

taminated with silver and is burnt in the process of extracting the silver. As photographic paper is made from the best quality rag pulp, a process which recovered that as well as the silver should be very valuable.

One of the most promising events of the year is the formation of the British Photographic Research Association, which has received the support of the great majority of firms engaged on photographic materials or accessories to their manufacture. Captain R. E. Slade, D.Sc., has been appointed director of research, with assistants, and is already at work. The council has adopted a broad outlook on the scope of the work to be undertaken, and valuable results should follow.

Negative Processes.

The chief lines on which attention is being directed are X-ray and colour-sensitised materials. In the former very little advance is evident during the past year. Messrs. Illingworth have introduced "Radioprint," a paper for X-ray negative work. Although this cannot be regarded as a general substitute for X-ray plates on account of the much shorter range and lesser detail which an image on a reflecting base must show in comparison with one on a transparent base, it offers distinct advantages for some work by reason of its greater lightness, portability, and freedom from breakage.

In the latter direction Ilford, Limited, have made a distinct advance with their new Special Rapid Panchromatic plate.⁴ In spite of its high speed this plate has a better general colour-sensitiveness than has been previously obtained, and other qualities such as gradation, good keeping, and freedom from veil have not been sacrificed. Some new principle has been adopted for its manufacture, but naturally the details of the process have not been published. The mechanism of the sensitising process is a matter of considerable interest for which as yet no satisfactory explanation is forthcoming. Seyewetz⁵ regards it as an accepted fact that in all cases there is the formation of a silver haloid-dye compound similar to a lake; in the case of plates treated with erythrosin, the formation of some such compound appears probable as the dye can be easily washed out from a fixed plate but not from an unfixed plate. To what extent Seyewetz has tested his statement with respect to dyes of the other classes which he mentions—triphenylmethane, acridine, quinoline, etc.—he does not state. It has also been generally assumed that a dye sensitises in the region of its own absorption, but this does not appear to have been carefully tested for at any rate the majority of sensitising dyes. The absorption is not easy to determine, since the colour of a dye solution often varies considerably with the solvent, it is not always the same in gelatine film as in water, and the colour of the dyed gelatine film itself is sometimes affected by drying conditions. The absorption would therefore need to be determined as it occurs on the sensitised plate, and this is made still more difficult in some cases—sensitol green and sensitol red, for instance—where, as mentioned by Renwick,⁶ the light-sensitiveness of the dye is very much greater when in gelatine film containing silver bromide than when in gelatine film alone. There is also the further question as to whether the colour sensitising process adds to the total sensitiveness of the emulsion or transfers a part of the existing sensitiveness to other parts of the spectrum. Considerably more evidence is required on all these points before definite conclusions can be drawn as to the nature of the process, and the complete explanation is probably bound up with that of the latent image, on which subject there is still much diversity of opinion.

For special sensitising to the infra red—as low as $9600\mu\mu$ —to allow of the photographic investigation of spectrum lines of metals, the U.S. Bureau of Standards⁷ found dicyanin to be the best sensitiser in spite of the chemical fog which it gives, but which for those special researches was not found inconvenient.

Processes for the after-treatment of negatives have been further studied in the Eastman Laboratory. Sheppard⁸ has shown the vary-

ing activities of different samples of ammonium persulphate as a reducer to be due to the varying iron content, iron acting as a catalyst in the oxidation of silver by persulphate, as Fenton showed it to act in the oxidation of organic acids by hydrogen peroxide.

Nietz and Huse¹⁰ have applied the work of Jones and Wilsey¹¹ on the spectral selectivity of silver deposits to the question of intensification. Where an intensifying process produces a colour change in the image, the full effect of this change will vary with the colour sensitiveness of the material by which it is to be tested or with the colour of the light by which it is examined. It is therefore only in the cases in which the colour of the image is unchanged that the visual intensification and the effective intensification are the same. A large number of the commoner intensifying processes were examined from this standpoint and their effectiveness determined; the results are unfortunately not capable of quite general application since the effect of an intensifier is partly dependent on the plate with which it is used, a fact which also slightly limited the scope of the investigation.

Colour Processes and Cinematography.

There is no serious advance to report in these sections. A large number of variations in detail are being constantly described and processes patented, chiefly by Americans. It is very difficult to estimate, for any one of these, what its value may be until a process actually in use embodies the detail.

Dufay¹² has brought out an improved method of obtaining a regular colour screen with very fine rulings, in which celluloid film is impressed by a lined roll at a temperature just high enough to soften the celluloid surface. Rulings as fine as thirty to the millimetre are obtained. Colouring is done by filling in the hollows with a greasy ink and staining the upper surface with an alcoholic dye solution. As the method is mechanical both for the depth of the furrows and for the staining, and as treatment of both sides of the celluloid film is possible, thus admitting of a four-colour scheme, it should be possible to get very satisfactory regular screens by this process. In other processes described there does not appear to be any actually new principle involved; they are chiefly variations in the method of combination of two or three images or of the production of a particular colour. The essential peculiarities of some of the processes are not easily seen, and in one case at least practically the same process was described by one American firm while it was being patented in this country by another American firm.

Theoretical and Experimental.

The standardisation of the measurement of the speed and other qualities of plates and papers, the desirability for which has been strongly urged in some quarters, and which at first sight would certainly appear to be a necessity, is by no means a simple problem, and it is not yet certain that it is even desirable. A paper by Huse¹³ on resolving power illustrates one of the difficulties of standardisation; he shows it to be dependent not only on the plate but on the exposure, the amount of development, and the developer. He used the fan-shaped converging grating and a definite scale of reduction, and obtained results to which a numerical value could be assigned. A range of 47 to 77 is obtained by variation of the developer only. Resolving power is also dependent on the colour of the light used, a maximum occurring in the blue, a minimum in the green, and a secondary maximum in the red. This variation is in the opposite direction to that which occurs with "gamma" (steepness of gradation), in which case, according to some recent experiments in the Ilford Laboratories, the results of which have not yet been published, a maximum occurs in the green, with minimum in the red and violet. It would seem probable that the variation in resolving power is connected with the opacity of the sensitive film, which, of course, varies with the colour of the light.

Jones and Wilsey,¹¹ in the paper already mentioned on the spectral selectivity of silver deposits, draw attention to the importance and wider bearing of the fact which had been well known for a long time, that the printing value of a negative varies with its colour, a yellow negative giving a more "contrasty" print than one with a similar

visual gradation but which is neutral in tone. This, of course, is due to the fact that the sensitiveness of photographic printing materials lies chiefly in the blue and violet region of the spectrum, and the distribution of this sensitiveness not being the same in all papers, it follows that the sensitometric constants of a plate depend not only on the plate itself and its development, but on the printing material with which it is to be used. The importance of this aspect is more evident in problems such as the comparison of different developers, or processes of after-treatment such as intensification (v.s.), where the colour of the resulting image may vary considerably.

The sensitometry of X-ray materials is still in a somewhat unsatisfactory position, very little work having been published since the preliminary note by Hodgson mentioned in the last report. One aspect of the subject has been studied by Miss Allen and Laby¹⁴ in Australia, but full details of their work do not yet appear to have reached this country. In the short outline of the scope of their paper given in *Nature* it is suggested that the effect of exposure is dependent on X-ray energy rather than on wave-length. This result is difficult to reconcile with the well-known characteristic radiations, which would have led one to expect very characteristic spectral sensitivity curves from X-ray exposures, and especially with results such as those obtained by de Broglie,¹⁵ who, examining by photographic means the absorption spectra of a number of elements, had first of all to determine the absorption spectra of silver and bromine as shown in the plate itself in order to allow for that effect in the other spectra. With so little of Allen and Laby's paper before us it is, however, impossible to discuss it thoroughly.

The relationship of the absorption of diffusing media with thickness has been studied from a mathematical standpoint by Channon, Renwick and Storr,¹⁶ and the results, confirmed experimentally, contradict the conclusion of Nutting ("Ann. Reports." 1, 313) that absorption in fully diffused light is proportional to thickness. Renwick has followed up the work by applying the results to a study of the behaviour of diffusing media (pigments) on a reflecting base.¹⁷ The general expression deduced is somewhat complicated; reflection density is given in terms of surface reflection, reflecting power of the base, maximum rejectance of the medium, the thickness or concentration of the medium, and the rate at which the maximum rejectance is reached. A much simpler approximation is obtained in the case of photographic prints, with almost black silver grains with which the maximum rejectance is very small. This expression was checked by experimental observation, and the agreement found was well within the range of experimental error. The expression previously suggested by Jones, Nutting, and Mees ("Ann. Reports," 1, 312), in which the reflecting power of the silver grains is neglected, is shown to be quite inadequate. The application to the general formula to black-image photographic prints is merely the simplest of the possible applications, and its scope may be extended to such cases as sensitive emulsions and coloured pigments, and even to paints, to go outside the photographic boundaries.

The density meter designed by Ferguson, Renwick, and Benson,¹⁸ which has several advantages over previously described meters, has aroused considerable interest. It is based on the law of inverse squares, has a horizontal viewing tube, a single light-source, a horizontal table large enough to admit of the reading of any part of a half-plate, is calibrated in densities, and will admit of readings up to a density of 2.8 or probably up to 4 with the introduction of a more powerful lamp such as the Pointolite. There is also a reflector for illumination at an angle of 45 degrees on the table of the instrument, a convenient device for the measurement of reflection densities. As the accuracy of the instrument is quite equal to that of other photometers it should find considerable use if it can be produced at a suitable price.

Helmick¹⁹ has obtained some further interesting results on the relationship between exposure and density, testing a suggestion previously made by both Abney and Kron, but without direct

experimental evidence. In ordinary plate-speed and characteristic curve determinations, logarithms of exposures are plotted against densities, the exposures being varied either by a time scale or an intensity scale. Helmick has plotted densities against times in a series of exposures in which time and intensity were both varied but in opposite directions, so as to maintain a constant energy, $It = \text{constant}$. He finds in all cases a maximum, i.e., for any given value of the product It there is a value of I and a corresponding value of t , which gives a maximum effect on the plate. The position of this maximum varies with the speed of the plate—the slower the plate the higher must be the intensity for maximum effect.

A considerable amount of attention is being directed, in America more particularly, to the properties of gelatine from two aspects. The first is the attempt to get really satisfactory and standardised methods of determining the physical properties of gelatines. The methods²⁰ are based on and are largely the outcome of those which have been found most suitable for the examination of glues. Apart, however, from the fact that certain minima of strength—setting-power, viscosity, etc.—are necessary and that a stronger gelatine is easier and more economical to work, it is the writer's experience that the physical properties are a very insufficient guide to the suitability of gelatine for making photographic emulsions. There are certain chemical differences between different types of gelatine and even between different batches of the same type, which are more effective than are the physical properties in determining speed, freedom from fog, and such qualities in different types of emulsion. As to the exact nature of these chemical differences there are very few available data, but it is very possible, if not probable, that they are due to the presence or absence of very small quantities of specific substances, rather than to variations in the proportions of the main constituents of the gelatine. A process such as washing the gelatine, for instance, will improve it for some purposes and spoil it for others. The final test of the photographic manufacturer is therefore in the particular emulsion for which the gelatine is required, and the safeguards of the gelatine manufacturer are care in selection of raw material and in its treatment.

The second aspect of the properties of gelatine is being considered largely from a biological standpoint, with the aim of assisting in the elucidation of life-processes. Some of the results have, however, considerable interest to the photographic industry. An instance of this may be cited in the results of Loeb,²¹ which should also be considered the work of Fenn²² on the precipitability of gelatine by alcohol and the effect on that of acids, alkalis, and salts, that of Fischer, Hooker, and Coffman²³ on the swelling of gelatine in polybasic acids and salts, and that of Sheppard and Elliott²⁴ on the swelling of gelatine in acids and alkalis, and the occurrence of reticulation in gelatine films. Loeb demonstrates the existence of gelatine compounds of the type gelatine-Na (sodium gelatinate) and gelatine-Cl (gelatine chloride) which are produced by the action of salts, acids, and alkalis, the properties of the compounds being strongly affected, however, by excess of reagent. For instance, if powdered gelatine is treated (a) with water 6 times, (b) with salt (NaCl) solution of $M/4$ or $M/8$ concentration 6 times, and (c) with the same salt solution twice and water 4 times, the amount of water absorbed is somewhat lower in b than in a but very much higher in c than in either of the others; the effect is permanent, the water absorptions being in the same ratio if the gelatines a and c are melted, dried, and again treated with water. The evidence points to dissociation of the gelatine-metal compound in water, which is inhibited by salts of univalent cations and much more strongly by salts of divalent cations, in proportion to the concentration of the cation. Similar results are obtained in the determination of viscosity and alcohol precipitation numbers (95 per cent. alcohol does not precipitate gelatine which has been treated with sodium chloride, and washed with water as in c

above). In the case of compounds of the type gelatine-Cl, the inhibition of dissociation by salts is determined by the nature of the anion and not by that of the cation. There is, of course, a very close analogy between the treatment of the gelatine in c and the washing of an emulsion or of a film to remove excess of salts, one of the commonest of photographic processes.

B. V. STORR.

Note.—As no attempt has been made in this report to refer specifically to every paper which has come to the writer's notice in the period covered, the following references to papers not abstracted in the Journal may be of interest:—Haines, "Cathode-ray Colours," *Brit. New Materials, &c.

Christmas Greeting Postcard Mounts. Sold by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

MESSRS. HOUGHTONS send us specimens of the Christmas card mounts which they are issuing for the forthcoming season, and in which they aim to cater especially for studios supplying portraits at popular prices. In this aim, as we are glad to see, they are not afraid from striking a note of cheerful colour in the design of the mounts. All of these latter are of the slip-in pattern and consist of folders the covers of which, in most cases, bear a colour design which in its vigour challenges the quiet and neutral styles of ornamentation of which no doubt the public has had enough. Of mounts of this quite artistically festive character we may instance Nos. 903, 904, 905, 906, and 907, each quite distinctive and each supplied at the price of 24s. per gross, or 154s. per thousand. Messrs. Houghtons' selection includes others of more reserved character, such as the series of folders designated No. X901 and No. X902 in which the postcard is inserted with a touch of adhesive along one edge and which are supplied at 12s. per gross or 77s. 6d. per thousand.

New Apparatus, &c.

A New Strip-Printing Frame. Made by George S. Moore, 73, Deamark Hill, London, S.E.5.

MR. MOORE, who for some years past has been a pioneer in the design and manufacture of apparatus for strip-printing, has recently shown to us a printing frame, just introduced, which embodies his latest design, and has been worked out in order to provide the most rapid manipulation without any sacrifice of accuracy in printing the photographer's name or monogram in the case of portraits, or the title of the subject in the case of view postcards. The frame consists of a most solidly made mahogany channel midway along which are provided spaces for the subject and title negatives. The subject negative is placed in a rotating holder, so as to allow it to be adjusted perfectly straight on the postcard. It is also fitted with postcard masks. Both these adjustments—of setting square and of masking—are most rapidly made, and the negative is held in the required position simply by turning a couple of buttons. For the exposure of the six-on strip the frame is fitted with a series of stops which are found to serve with quite satisfactory accuracy in bringing the strip into position on the negative. Working from left to right, a series of eight exposures produces the six postcards on the strip, the simple release of the pressure of the hands on the spring back sufficing to allow of the bromide paper being freed for drawing forward into the next position. The work of the printer, as we have seen from a number of specimens, is most accurate, and the apparatus can be used in conjunction with the foot-pedal printing box of Mr. Moore, or, indeed, with any printing box fitted with separate device for the switching on and off of the light. Most solidly and substantially made in mahogany, the price of the apparatus is £5, carriage free.

Royal Photographic Society. "The Tower of London." E. W. Harvey Piper.

CROYDON CAMERA CLUB.

MR. H. GUY JOHNSON last week gave a capital demonstration on "Workshop Aids," the main part of which bore no relation to photography. Nor did he claim anything to be new, stating that most of the "aids" were as old as the hills; but as they were fresh to many of lesser age, the demonstration lost none of its value in consequence. All learnt something.

Who has not experienced a lens cell obstinately sticking at some time or another. Here is the remedy for the evil: Take a piece of thin wood, cut out a circle a shade larger than the outside

diameter of the lens cell, and then make two saw cuts about half-an inch apart, as shown in the diagram. By inserting the lens cell in the circular aperture, and gripping the wood at the other end, the cell is firmly held, and rotating the strip of wood anti-clockways, unscrews it.

A very neat way of cutting a circular aperture in a lens panel consists in drilling a small hole right through at the centre, and then employing an "adjustable washer cutter" in an ordinary brace. At half-time reverse the wood and repeat on the other side. These cutters are handy tools for the camera craftsman, and, he said, by no means expensive. All who employ a fretsaw for the same purpose may not be aware that much stouter saws than the normal—called "power blades"—are obtainable.

Among other tips a "one drop" oil can was shown, improvised out of a tabloid bottle, with a piece of wire soldered inside to the screw-on cap. This wire is flattened at its extremity, and dips into the oil contained in the bottle, and permits of one drop of oil being placed exactly where wanted. Regarding the well-known plan of waxing wood benches to make them waterproof, the demonstrator pointed out the necessity of incorporating with the paraffin wax a small quantity of beeswax; otherwise it ultimately breaks up into small fissures, and penetration of solution occurs.

On the question of the much-debated soldering of aluminium, he said that he had found "Kayolin" quite satisfactory. The secret is to keep the wire brush (supplied with the solder) moving backwards and forwards all the time the solder is being heated until the latter flows. It was also applicable to "Duralium," a wonderful alloy, possessing valuable features in many directions. Praise was also given to "Ernoid," a substitute for ebonite, but far easier to work and capable of receiving a fine surface by polishing by hand.

The formal opening of the session took place the previous week, the president, Mr. John Keane, being billed to deliver an address. Neither he nor the secretary nor the vice-chairman turned up, and the "office boy," backed with the moral support afforded by the refreshment department, stepped into the breach with a critical review of the characteristics of the absent executive officers and old members, ostensibly for the benefit of new members, who are many indeed. Looking at his contribution in as favourable light as possible, it may be confidently stated that, if recorded verbatim, it would expose this journal to a dozen or so actions for slander.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

The first meeting of the session 1919-20 was held on Monday, October 6. Mr. E. D. Young in the chair. The Secretary read a report on the work of the society during the past year and a-half; and Mr. Shiels, in moving the adoption of the report, made reference to the good work of the society since its inception in May, 1918. The statement of accounts was also read and adopted.

The Chairman then explained a proposal on behalf of the committee. It was felt by them that the duties of the secretaryship now being considerable it would be advisable to secure a permanent secretary, who would undertake the work in consideration of a fee or honorarium. The society's solicitor had been approached on this matter, and he had expressed willingness to undertake the duties if the members were agreeable. This arrangement, Mr. Young explained, would involve the raising of the annual subscription to one guinea, and it was proposed that the sum of a guinea and a-half should cover the subscription of a firm where there was more than one member. This proposal was carried unanimously. A point was then raised as to the voting powers of members, i.e., whether each should have one vote, or whether the arrangement should be one vote per firm. This latter suggestion was agreed upon by a majority of twelve to five.

Mr. Swan Watson, in a few words of appreciation of Mr. Young's services as chairman, moved his reelection. Mr. Campbell Harper seconded. There were no further nominations. The following members of committee were then elected:—Messrs. Campbell Harper, Bambrick, Moffat, and Miss Gray. Mr. Young thanked the meeting for electing him president for the ensuing year. He had the society very much at heart, and he hoped to see a very successful season.

A few minor alterations to the rules and constitution of the society were then proposed and agreed upon.

Mr. Young then reported on the retouching class. This had commenced most successfully on October 1, and the membership now stood at sixty-two. Mr. Young explained that he had felt somewhat overwhelmed at this unexpected number of applicants; but he hoped soon to be able to cope with the size of the class. It was possible that he might require to secure the services of an assistant. This matter would be placed shortly before the Board of the College of Art. He explained that he would seek to instruct the pupils in the sound basic principles of retouching, and it would necessarily remain for each individual photographer to guide his assistant in the particular style of work which he was in the habit of doing. It was proposed that a committee of master photographers should be appointed to look after the interests of this class, and at as a deputation to the Board when occasion arose.

Mr. Swan Watson then reported upon the decisions of his Apprentices Committee. They had agreed at present upon three main points:—

1. That an apprentice should be indentured for a period of four or five years, according to his age at the commencement of his term of apprenticeship. Thus a boy of fifteen or sixteen would serve for five years; but one of seventeen or eighteen would probably be able to cover the ground required in four years.

2. That there should be in all indentures an option on either side to break the agreement after a period of six months.

3. That the master should stipulate in each case as to the branches to be acquired during the term, stating a minimum period of instruction in operating.

Further than this the committee were unable to go in the mean time until they had acquired a more intimate knowledge of the new Scottish Education Act. On a motion of Mr. Shiels, seconded by Mr. Macalpine, the matter was remitted to the committee for further consideration and information. It was pointed out that when the new Act came into force all assistants and apprentices under eighteen would attend day classes, and, if suitable classes were not by that time organised by photographers, assistants would be compelled to attend the classes of what the authorities might consider the nearest allied trade. Such classes might not be of the value to assistants that actual photographic classes might be. Mr. Young hoped that soon a technical class on photography might be arranged.

The question of special power rates for electric current consumed by photographers was raised, and a copy of a letter was read which showed such an arrangement had been in force in Glasgow for fourteen years. Mr. Shiels proposed that a deputation be sent to the town council on this matter, and he himself hoped to be able to report in more detail at the next meeting. Meanwhile, it was suggested that the secretary might communicate with the town clerk on the subject. A discussion also took place on the question of water supply, and it was pointed out that the Trust were fitting meters to the supply where possible.

A letter was read from Mr. Scott, of Kodak, Ltd., intimating that the photographers of Glasgow wished to arrange a golf match with the Edinburgh professionals. Members were invited to go through to Glasgow for the afternoon, play a round of golf, and participate in a dinner in the evening. The photographers of Glasgow had had some idea of forming a society similar to that existing in Edinburgh, and it was suggested that this would be a suitable occasion on which to discuss the matter. Over a dozen members expressed their willingness to meet their western confrères. The question of the Edinburgh Professional Exhibition, billed for the evening, had to be held over through lack of time. The meeting then concluded.

NOTE.—My attention has been drawn to a recent P.P.A. handbook in which had been discovered one of those flashes of Southern humour which delight us so much by their originality—namely, a pointed rally against the "native canniness" of the Scot. I gathered from the allusion that the trait, in this instance, was exemplified by an anxiety on the part of Edinburgh photographers to send apprentices to a technical class in order to escape the burden of personal tuition. There are three known jokes south of the Tweed; and this, believed to be the most popular, has been found to possess a recurrence which may be anticipated with almost mathematical accuracy.

PELHAM S. MOFFAT, Hon. Sec., E.S.P.P.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Notice is given that the partnership between Mark Owen Athey and Charles Schofield Sykes, carrying on business as photographers at 7, Nevill Street, Southport, under the style of Athey and Sykes, has been dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by Charles Schofield Sykes.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—In consequence of the railway strike the general meeting of the society previously arranged for September 30 had to be postponed, and will now take place on October 23, at 3.30 p.m., at Queen's Hotel, Promenade, Southport. The arrangements made for the previous date apply also to the postponed meeting. A social evening to which ladies are especially invited will follow the general meeting, whilst those members who can put in a day at Southport and would like a morning's golf should communicate at once with the honorary treasurer, Mr. F. Read, 14, Balfour Road, Southport, who is in charge of the local arrangements.

News and Notes.

TRAILL TAYLOR LECTURE.—The twenty-second annual lecture under the Trill Taylor Memorial Trust will be delivered at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1, on Tuesday, October 21 next, at 7 p.m., by the Rev. A. L. Cortie, S.J., F.R.A.S. Father Cortie, who is director of the Stonyhurst College Observatory, will take as his subject "Photographic Evidence for the Formation of the Stars from Nebulae."

NOTTINGHAM AND NOTTS. PHOTOGRAPHIC SOCIETY will hold their sixteenth annual exhibition of photographs and lantern slides on November 20 to 22 next in the rooms of the Nottingham Society of Artists, 11, Park Row, Nottingham. There will be an open section in addition to that for members only, and the secretary is very anxious to have a good selection of exhibits. The closing date for entries is Saturday, November 8; exhibits to be delivered on Wednesday, November 12. Entry forms and further particulars can be obtained from the honorary exhibition secretary, Mr. A. Beeston, 103, Nottingham Road, Nottingham.

DEATH OF MR. PHILIP E. B. JOURDAIN.—We regret to see the announcement of the death, on October 1, at the early age of thirty-nine, of the talented Cambridge scholar, Mr. Philip E. B. Jourdain, who contributed extensively to mathematical research despite the paralytic disease which had afflicted him almost from childhood. Mr. Jourdain was also a linguist of some note, and the writer of many papers on the history of science. He showed a considerable interest in the literature of photography by his papers and translations, many of which appeared in the "British Journal" up to within some ten years ago. Thus, his notes on processes of direct photochromy, which appeared in our columns in the year 1900, form a valuable partial bibliography of this subject. He also contributed a good deal to the literature of the interference process of colour photography, and further showed his interest in the more everyday problems of photography by a series of notes on the efficiency of photographic shutters.

LECTURES ON THE SOUTH PACIFIC ISLANDS.—All those who have felt the fascination of the South Sea Islands from the novels of Jack London or the more serious pictures of island life in works such as those of R. L. Stevenson or Mrs. Grimshaw, will note with interest the series of three lantern lectures to be delivered at the Royal Photographic Society, the first on October 15 at 8 p.m., and the two succeeding on October 22 and October 29 at 7 p.m., by Mr. Thomas McMahon. Mr. McMahon is a great traveller in the islands, where he has had the opportunity of studying the native peoples most intimately. At the same time he takes a strong interest in the industrial possibilities of the South Pacific, and will have much to say on the importance of the islands to those of the English race, and will be able to show the far-reaching steps taken by the Germans before the war to secure economic supremacy in these parts of the world. The exhibition of the Royal Photographic Society, which opened on Monday last, contains a special section consisting of a large series of photographs by Mr. McMahon showing the customs, industries, and natural resources of the islands.

THE SCOTTISH SALON.—The prospectus of the twelfth Scottish National Salon has now been issued. The exhibition will be held in the People's Palace Galleries, Glasgow, from December 20 to January 24. Our Scottish friends have considered it best to suspend the exhibitions during the war, but are now leaving no stone unturned to make the forthcoming exhibition a record one in the successful series which the past has witnessed. The entry form may be obtained from the secretary, Mr. John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow, and must be returned to him not later than Monday, December 1. The exhibits themselves require to be addressed to the Photographic Salon, The People's Palace, Glasgow Green, Glasgow, and to arrive not later than Tuesday, December 9. An entry fee of two shillings is charged, and suffices for any number of exhibits up to a total of eight. Any further exhibits require to be entered on additional entry forms, and to be accompanied by a further remittance of 2s. for each eight exhibits or less. It should be mentioned that the Salon is limited to the work of photographers of Scottish nationality: exhibition of

pictures by non-Scottish workers is a matter of special invitation. The board of selection this year will consist of Messrs. Arch. Cochran, Alex. Keighley, and J. M. Whitehead.

PORTRAITS IN WATER-COLOURS.—We recently had an opportunity of seeing a large selection of the work of Messrs. Robinson and Co., 17, 19, and 23, High Street, Harlesden, London, N.W.10, in the making of portrait enlargements finished in water-colours. Messrs. Robinson make a specialty of water-colour finishing, and in these days when so much wretched work in the way of enlargements is made, it is a pleasure to examine portraits which represent at once such a high degree of artistic taste and technical skill. The specimens which we have seen included both portraits with the customary solid background and those in the sketch style, which latter displayed to particular advantage the artistry of Messrs. Robinson's work in drawing, as well as in colouring. While their styles are most of them upon the lines familiar to photographers, we should not omit to mention a specialty of their own which they call "grey panel" effects, in which the background is a light tone of grey or buff, which, in their hands, goes exceedingly well with their colour work. These portraits impressed us as something most artistic and at the same time quite distinctive. It should be added that Messrs. Robinson make no claim to be "rush" makers of enlargements; their work is turned out as speedily as its artistic character permits, and usually can be delivered within about three weeks of the receipt of the order. It is just as well that the fact should be mentioned, because we are satisfied in our minds that photographers wishing to offer their customers really fine water-coloured enlargements will have no cause to regret placing their commissions with Messrs. Robinson, whose price list, just issued, fully specifies their charges for these portraits, as well as for those in black and white and for straight enlargements.

PRESS AND PORTRAIT PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Your leading article on the professional operator and his activities, which you so naively and alliteratively refer to as the Press photographer poaching on the preserves of the purely portrait photographer, is interesting. Since you so courageously look to the interests of the P.s, perhaps you will be good enough to let me defend the Q.s.

It is perhaps unfortunate for the portrait photographer who, having struggled with his lumbering apparatus, discovers a photographic Puck at the reception with proofs of his diligence and enterprise. But if the aforementioned Puck is poaching on other preserves, he is but returning the compliment. A visit to the art room of the newspaper any morning will assure you of the fact that sometimes the portrait man is the poacher. In any case, it seems to me that a professional photographer is entitled to widen the scope of his profession as and how he can; and there is not a lot of difference between a portrait firm running a Press department and a Press firm running a private order department.

The Fleet Street professional specialises in Press photography, but he is not obliged to concentrate on that or any other branch. As a result of his enterprise and initiative he is able to "deliver the goods" at an opportune time, and he is entitled to any requital which comes his way. As you say, the *modus operandi* of the Fleet Street man is not denied the portrait photographer, although it is to be admitted that a man who rolls up at an appointment three-quarters of an hour late would probably view the necessity of adopting such hustling methods with no little trepidation. With the customary enterprise of the portrait photographer, the gentleman with the stand camera and elastic conceptions of appointments will probably hope for the elimination of the hustler along the lines of convention, as outlined in your article.—Yours faithfully,

LAURENCE H. CADB.

13, Cliffords Inn, Fetter Lane, London, E.C.4

REVERSAL OF FILM NEGATIVES.

To the Editors.

Gentlemen,—In the last number of the "B.J." of August 22, just to hand, there is an article with the above heading, which I have read with much interest, having had a similar experience to the writer of that article. While on a trip some years ago around the Dead Sea by motor-boat a small Kodak was taken along for the purpose of making snapshots of the party. Larger plate cameras were used for taking the views. All plates turned out very successful, but among the films there was an exposure on one of the rolls which has to this day puzzled us. On the east side of the Dead Sea there is a small plain called Ghor et Megraa. Here there is a thermal sulphur spring, with a pool in which the natives bathe, and in order to protect themselves from the direct rays of a tropical sun, an arbour has been built. While some members of the party were indulging in a bath here an exposure was made, due allowance being made for the dense shade. On the roll five exposures turned out good negatives and the sixth one a splendid positive!

The heat of the Jordan Valley, I think, will become proverbial after the prolonged stay there recently of British and Australian troops, and if it is the radiation of heat in and around the camera which penetrates to the sensitive film and produces over-exposure, then anyone who has visited the valley in summer time would declare that the heat there is certainly great enough to turn all films—and why not even all plates?—exposed there into positives!

Further notes, however, on this subject, I think, will be read by many other photographers beside the undersigned.

H. L. LARSSON.

American Colony, Jerusalem, Palestine, Sept. 13, 1919.

THE SALE OF VIEW POSTCARDS.

To the Editors.

Gentlemen,—A few weeks ago you had an article on the sale of picture postcards and advocating pushing the photo-postcard, so that the public would buy photo-cards rather than colotype or other kinds, including the "colour-trosities" (this is not a Geddes new word). The reason the public buy these cards is on account of cheapness, educated in such by the past insane cut prices of pre-war producers of the pictorial postcard. The humble penny is the public's estimate of the value of these things, and I have seen in a well-known stationer's not far from Ludgate Hill twelve postcards of London, sepia-toned, for sixpence, and this some time in 1918. Rank profiteering! Where is the photo-controller and tribunal!

Nowadays the public won't pay 2d. and 3d. which Mr. Philip G. Hunt suggests photographers should charge (2d. to get 50 per cent. profit); but when he suggests 3d. and 125 per cent. profit—Oh! I see his dodge; he wants to get us all locked up for profiteering. Rank traitor to the cause!

Again, if the public want photo-postcards they go to the stationer's as a rule, seldom to a photographer's shop. At least, that was my experience some years ago when things were cheap. I took a good series of photographs of the locality I was in, views and events, yet I had comparatively few sales, although I had a showcase on the wall outside. I sold more in lots to local stationers, so I discontinued it and encouraged the stationers, etc., to take more. It paid better in the long run at that time when a penny was a penny and not a third of a farthing.

I think myself the bulk of the picture postcards are bought by the public, not by the "upper ten" grade of society, and the printed and coloured cards are selected because they serve the purpose and are cheap, and also because the present rate of postage makes it an expensive item to send off, say, six cards at 2d. and postage 1d. each. This is 1s. 6d., and if the cards are 3d. each the cost will be 2s. Holiday-makers are the most prolific users of postcards, and now they have to economise, especially at the seaside. Visitors to a locality buy most of the general views, and no doubt these have the biggest sale.

I enclose a photo-postcard with quotation on back, 37s. per 1,000 semi-matt, black, in 1912. We now pay 100s. per 1,000 for finished cards, a big difference in cost, and so we can't risk having these left on our hands as too expensive to sell. Shops won't buy them on spec. They say they have no great demand for photo-cards, but more for cheaper ones. Photo-card printers buy cards in larger

quantities than we can, and get a better discount for cash, yet we can often do cards cheaper by the gross. A better profit is made out of the photographer very often than the photographer can make out of the shops, and therefore the photographer hasn't sufficient inducement to risk unsaleable stock.

Mr. Hunt recommends on one page and advertises on the next, a coincidence no doubt. Still, a photographer knows his locality as a rule, and if he could retail cards would do so. And again, to show photo-view-cards in your window at 2d. and 3d. each beside portrait postcards at, say, 7s. a dozen, would make the public ask why. They don't analyse how it is done, think the photographer is putting on the price, and pass on their way. So it is best to keep the view cards at 2d. and 3d. each out. Explanations are not then needed to show to a customer why you can't do portrait cards cheaper. Your business is then purely a portrait business, so far as the public is concerned, and it is accepted as such. That is my experience of the combination of postcards in 1912 and now.—Yours faithfully,

F. S. WHEELDON.

239, Shernall Street, Walthamstow, E.17.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. T. W.—We suppose your poster and showcard work would not be offered publicly to anyone, but would be done for individual traders. In that case there is no necessity for you to obtain a licence, which, we suppose, is what you mean. Registration is altogether different, and is necessitated only if you do not trade under your own name.

A. B.—About four 1,000 c.p. half-watt lamps. These should be capable of being raised or lowered between, say, 7 ft. 6 ins. from floor to 5 ft., the latter height being necessary to allow of very short exposures for sitting figures and children. You will find it economical to get a quicker lens, say $f/4$, for very short exposures than to install more lamps.

H. H. P.—Your room is rather too short for full-length portraits, but will do very well for heads and half-lengths. Half-watt lamps can be obtained from the General Electric Company, 67, Queen Victoria Street, London, E.C. For a great deal of your work the daylight from the window will be sufficient. For full lengths the half-watts might be used as a top light in conjunction with the daylight.

E. B.—We fear you would be able to do nothing with flashlight, as the flash is not quick enough for rapidly moving objects, and even if you succeeded in synchronising a focal-plane shutter with the flash, the plate would probably be under-exposed. The only thing to do would be to employ a large number of arc-lamps, and perhaps, in addition, some mercury-vapour bulbs, as is done in cinema studios.

N. B.—The yellow spots have the appearance of being due to desensitising impurities in the raw base. The methods for avoiding the defects are rather outside our province, but we imagine they will consist in better baryta-coating or in the addition of anti-desensitisers to the emulsion, as dealt with recently in the "B.J." by Mr. W. C. Mann. From the look of the prints under a magnifier the paper seems to have very little baryta-coating.

J. G.—There is no book on studio reconstruction and decoration except the little manual "The Portrait Studio," issued by our publishers, price 10d. post free. As regards electric lighting with half-watt lamps, we had a rather comprehensive article in the

"B.J." of October 26, 1917, which you can still obtain, price 4d., and the General Electric Company, 67, Queen Victoria Street, London, E.C., have also a gratis booklet dealing with the types of installation which are recommended.

A. N.—For subjects of the kind you describe, by far the best developer is pyro-ammonia, owing to the slightly warm black of the tone and transparency of the shadows. Amidol, owing to its cold black tone, is about the least suitable. Moreover, you will find that there is no developer which will give satisfactory lantern slides unless it is used at a normal temperature. The best advice we can give you is to use the pyro-ammonia formula advised by the maker of the lantern plates. These latter, for the best results, should be of the slow variety.

J. H.—We should say that unless you want to give very short exposures, three 1,000 c.p. lamps will be sufficient for your studio. We should place one about 8 ft. high about 8 ft. from the background, nearly opposite the centre of the latter. Another lamp should be opposite the edge of the background, about 5 ft. away, and the third lamp midway between. These two lamps may be a foot or eighteen inches lower than the front one. If possible, have all lamps made to raise and lower, as this will give more control over the lighting, and allow you to get shorter exposures with sitting figures and children.

O. A.—Any method of putting titles on negatives with opaque calls for neat draughtsmanship and some experience in putting on the lettering reversed, so that it will appear correctly in the prints. The method most usually employed by makers of view postcards is to have the lettering drawn very big or set up in type and photographed down to the requisite size on a press plate. A lot of titles are photographed on one plate, and the film on the negative is then cut through to the glass in strips with a sharp knife and the strips then detached from the glass with hydrofluoric acid and laid on the view negative.

F. T.—The dimensions of studio which you give should be quite large enough for single pieces of furniture, but would not do for suites, for which you would require much greater distance in order to preserve the proper proportions. We assume that you intend to use the studio for portraiture as well as for furniture. We should advise about 15 ft. of glass in top and side light, the latter coming down to 3 ft. from the floor. For the furniture we think a run of glass on the solid side of roof, say 5 or 6 ft., would be very useful so as to equalise the light over a large piece. If the studio were for furniture alone the old "tunnel" form could not be improved upon.

J. R.—(1) In the circumstances you name we do not think a licence is necessary, if it is understood that your advertising and canvassing is in the general Press, and extends generally throughout the country, but is not of a local character. (2) If you open an office so that anyone in your district can walk in and give you orders for work, then we think that you require a licence. Certainly you would if you made a display of your work. The Licensing Order is not very explicit on the particular questions you have raised. It is plainly defined as not applying to businesses carried on with a particular class of traders, and that is what your business particularly corresponds with.

C. R.—You can get a much better result by dulling the metal surface with putty, but it is not the best method. The best method is to arrange a small tent of muslin round the shield, so that objects are prevented from being reflected in it. Then you can strengthen the lighting from one side or another to give any necessary relief to the lettering by bringing any strong artificial light, such as a half-watt or arc-lamp, near to the outside of the tent. You will find this method described in some detail in the little book, "Commercial Photography," which our publishers issue, price 1s. 2d., post free, and which is a handy volume for hints on photographing these miscellaneous subjects.

H. H.—The gas mantle must not be fixed at a given distance from the condenser, because in order to get a clear illumination its distance from the condenser will vary slightly according to the degree of enlargement. You can reduce to some extent the necessity for this movement by inserting a ground-glass screen as near as can be done without risk of fracture to the gas mantle. An

opal screen would be better still, but cuts down the light tremendously. The negative, as a rule, should be as close in front of the condenser as you can put it. It is only if the negative is very much smaller than the condenser that there is an advantage in putting it further forward so that you get a more concentrated beam of light on it and thus shorten exposure. Retouching marks on the negative are minimised by diffusion of the light in the way already described, that is, with the ground-glass or opal screen close to the illuminant.

T. L.—The inverted half-watt fitting is a very wasteful one as far as current is concerned, although it gives very soft effects. About four 1,000-c.p. lamps should give you all the light you need if run at full voltage. It seems foolish to handicap yourselves with such a slow lens. We should recommend at least an $f/4.5$ lens, as this with the same light and plate will only require one-third the exposure of one with an aperture of $f/8$. Use thin calico as a diffuser, and have the lamps to raise and lower; the low position will greatly shorten the exposure for children. We should keep the walls light; it is easy to put dark curtains or screens, if needed, to cut off surplus reflection. A useful arrangement of lamps is one opposite centre of background about 8 ft. high, 7 ft. from background, and the other three in a curve from this to the side of the studio, the last one being about 5 ft. from the end wall. These side lamps may be a foot or so lower.

W. G. A.—(1) If the iron is dissolved in the water we do not think it will cause any difficulty, but if it is in the shape of iron or rusty particles you must have the tap fitted with a filter, for which there is nothing better than a bag of flannel tied over it. (2) The persulphate reducer is liable to be erratic if kept long after having once been used. We prefer to make it up fresh for each time of use. (3) With either pyro-ammonia or pyro-soda the best thing for under-exposure is to use the normal formula, but diluted with three or four times its bulk of water. This will avoid your getting such very dense and contrasty negatives, especially with pyro-metol. You will get just as good shadow detail with pyro-soda as with pyro-metol. From what we have seen of your negatives we should advise you to leave pyro-metol alone and stick to pyro-soda, which does not so readily yield the great density and yellowish colour which are characteristic of pyro-metol.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)				

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.

The insertion of an advertisement in any definite issue cannot be guaranteed.

SUMMARY.

The 1920 "Almanac" is now in an advanced state of preparation. Those who have not yet signified their wishes as to advertisement space in it will greatly oblige our publishers if they can do so at the earliest convenient date.

In a contributed article Mr. Vivian Jobling describes a most handy appliance for facilitating the accurate mounting of prints and the trimming of mounts. (P. 622.)

The pictorial section of the Exhibition of the Royal Photographic Society, of which Mr. F. C. Tilney contributes a personal impression, is notable for three or four small but exceedingly choice pieces of work in oil or Bromoid transfer by Mr. Fred Judge. (P. 616.)

In a leading article we deal with the absence of all formalities under the present Copyright Act in the creation of copyright in photographs and other works as a form of property. In proceeding to refer to the circumstances which determine the ownership of copyright thus created, we deal with some of the doubtful cases and point out how, under the present Act, they present a lesser degree of difficulty. (P. 614.)

A contributor, "Thermit," utters a plea for greater perfection in negative-making, and instances items in the making of negatives which seem to him to require emphasis. (P. 619.)

In his article this week "Practicus" deals with the use of flash-light in studio portraiture, pointing out the conditions which require to be observed for successful lighting and advising various practical expedients for dealing with ignition of the powder and the smoke nuisance. (P. 617.)

A host of hints on the taking of photographs to illustrate flooring and wall-covering in tile work are contained in an article on page 620.

A correspondent warns photographers against purchasing from pawnbrokers at the present time R.R. lenses bearing a well-known name unless full opportunity is given of testing the performance of the instruments. (P. 627.)

The Coventry Camera Club has made and handed over to its city's library a collection of photographs illustrative of scenes in the life and writings of George Eliot. (P. 619.)

At the Royal Photographic Society on Tuesday evening last the Rev. A. L. Cortie delivered the twenty-second Traill Taylor memorial lecture, taking as his subject the photographic evidence for the formation of the stars from nebulae. (P. 625.)

An oil heater for the dark room, which is efficient and can be improvised from materials ready to hand, is described in a paragraph on p. 613.

Some preparations found effective in the protection of silvered surfaces yet without detriment to their optical quality are mentioned in a paragraph on page 614.

EX CATHEDRA.

The Weekly Almanac. Perhaps even those firms accustomed to getting a goodly proportion of their business through advertisements in the "B.J. Almanac" have not realised the fact that among many photographers in distant parts of the Empire the "Almanac" is always referred to as the "Journal." Why, we do not know; perhaps the second word of the title is seized upon as sufficient. But the fact is significant; it signifies—what every regular advertiser in the "Almanac" knows—that the book is in use throughout the year; that, so far as a business firm in England is concerned, it performs the duty of a weekly circular or journal reaching the hands of a photographer in Tasmania or Trinidad fifty-two times or more during the year. Possibly the persistence of the advertising effect of an announcement in the "Almanac" is not so fully appreciated as it should be by those who have not advertised in it. Yet it is the common experience of firms whose announcements appear in the book and who, moreover, will often get orders for goods which were advertised only in an issue of the "Almanac" three, four, or ten years back. Those who seek for some explanation of this unique and long-continued advertising power need not go far to find it. It consists in the fact that a book of the size and everyday usefulness of the "Almanac" is kept at hand year by year and regularly consulted as a universal "inquire-within-upon-everything" in matters photographic. It is kept not only for the sake of its practical information but for its services as a guide to what is obtainable from British photographic firms. When it is considered that this all-the-year-round service can be bought for as small a sum as a shilling a week, it is not surprising that advertisements in the "Almanac" should run to their great number and should include those of the smallest as well as the largest establishments in the trade.

* * *

Warming the Dark Room. The time of year is fast approaching when most photographers will desire to warm their dark-room in some way. The installation of a gas stove will be found to be a fairly expensive item, and the same may be said of its maintenance. For some years we employed, in a country district where no gas was available, an improvised form of heater that was most economical in use. It consisted simply of a small oil lamp having a wick of about an inch in width, and three flower pots, ranging in size from about ten, twelve, and fourteen inches across the rims. To use the heater proceed as follows:—Light the lamp, trimming the wick carefully, in order to permit of an even smokeless flame. Three blocks of wood are placed in the form of a triangle, the lamp being in the centre. The largest pot is inverted over the

lamp, so that the flame of the lamp is in a direct vertical line with the drainage hole in the pot; the other pots are then put on over the first, according to size, having the smallest at the top. In practice the pots get very hot, and provide a large heating surface. The cold air enters the heater from the bottom, passes over the lamp flame, and out at the top of the upper pot. The heater is practically light proof, leakage of light at the bottom being too small in area to do any harm, while that at the top may be completely stopped when required by putting any form of cap over the hole. Cleanliness in filling and trimming the lamp will entirely avoid smoke and smell, while even when the heater is kept on continuously a gallon of oil a week will be ample.

* * *

Negatives for Enlargement. A great deal of work in the finishing of enlargements would be saved if a little more care were exercised in the production of the negative. A good average negative direct from nature, if enlarged upon suitable paper, will give a result which requires little more than spotting, but unfortunately most enlargements have to be made from copy negatives, and these often leave much to be desired. As a rule such negatives are thin and lacking in contrast, and this we believe to be due to two principal causes: the use of a rapid plate and insufficient development. Under-exposure is another common error in copying, and this is often due to not making allowance for the yellow tint which forms the basis of nearly all old photographs. A clean-looking negative, even if rather thin, will usually give a good enlargement, as any small portions of clear glass in the shadows seem to have more effect on the contrast than they do in contact printing. It is a good plan to use a non-staining developer for negatives for enlargement, as the colour of copy negatives varies, and it is very difficult to allow for this by artificial light. In some cases two negatives will appear identical when viewed by the light of a filament lamp, but when compared in daylight it will be seen that one is much yellower than the other, and needs perhaps three times the exposure.

* * *

Protective Coatings for Mirrors.

A note by F. Kollmorgan in a recent issue of the "Journal" of the Optical Society of America reviews our knowledge of the means which can be taken to prevent the tarnishing of surface silvered mirrors without appreciable interference with their optical quality. In the use of a reflex camera the preservation of the silvered surface in an untarnished state is of course a chief factor in maintaining a brilliant image on the focussing screen. It is mentioned that a thin coating of bichromated gelatine is capable of protecting a silvered surface for twenty-four hours from the action of sulphuretted hydrogen. A more usual coating is one of celluloid dissolved in amyl acetate, but, apparently, a preparation which is better in some respects is a commercial lacquer sold in the United States as Lastina. A parabolic reflector at the Harvard Observatory after three months' use under this coating was found to retain 70 per cent. of its original reflecting power. The lacquer is used thinned down with from two to six times its volume of commercial thinner. Apparently, while offering a substantial protection to the silver from atmospheric influences, the lacquer coating itself is very soft and most readily scratched, so that any dust settling on the mirror requires to be most carefully removed by means of a fine camel-hair brush. It would seem that while the lacquer may be a better preparation for astronomical instruments, a very thin coating of cellu-

loid varnish is superior for silvered surfaces, such as the mirrors in reflex cameras, which are more exposed to chance access of dust.

* * *

Marking Time.

It is a sad fact that most photographers, at a comparatively early stage in their career, seem to arrive at a dead level in their work, and never produce anything of outstanding merit afterwards. This is to be regretted, for it is not to be imagined that even the cleverest artists could exhaust the possibilities of photography in a few years. Very often we fear that it is due simply to commercialism—that is to say, that the photographer has his eye on the order and not on the picture. We believe that it would be of great benefit to portrait photography as a whole if its professors went in more strongly for exhibiting their work at the annual shows. Nothing is more likely to make a man realise the insipid nature of his ordinary work than to look round for a picture which he can show in competition with others, and if he has the ability nothing will stimulate him more to further effort. To rest upon the fact that customers accept the work offered without complaint or even with approval is not enough, it is only marking time and not progressing from good to better. We hope, therefore, that the next show at the P.P.A. Congress will be a good one, and that it will be well patronised, not only by amateur photographers, but by potential sitters.

CREATION AND OWNERSHIP OF COPYRIGHT IN PHOTOGRAPHS.

It is a somewhat well-worn theme, but as we are still constantly asked by readers of these pages to "make the enclosed photographs copyright," it seems still necessary to set forth plainly the difference between the present Copyright Act and that of 1862, which was repealed, with the exception of one or two sections, on the coming into force of the present Act. Under the old Act copyrights were registered at Stationers' Hall, and most of our correspondents evidently think that the abandonment of this formality renders their ownership of copyright less secure or less definite in some way or other. Such, however, is not the case, although at first sight it may seem so. There is an important difference between the two Acts in this respect, but the difference is not one of greater or less security of title in the copyright in the photograph. Let us explain as plainly as we can in what the difference consists. Under the 1862 Act registration of the copyright at Stationers' Hall was a necessary formality before any action could be taken or any penalty recovered in respect to infringement of the copyright. Under the present Act action for infringement may be taken at any time after the creation of the copyright. This is practically the only difference which the abolition of registration makes to the photographer, and it will be clear at a glance that it is a difference entirely to his advantage. Under the 1862 Act few photographers thought it worth while to register every photograph, copyright in which was their property. Yet omission to do so often precluded them from taking action for infringement. It is this disability which was removed by the present Act.

But we can hear our correspondents replying: "Very well, if that is so, what is there to show that the photograph is copyright or that the copyright belongs to us?" The answer is to read the Act. Section I. of the Act sets forth the general provision that under certain conditions copyright subsists in every original literary, dramatic, musical, and artistic work, photographs being specifically included in artistic works. The conditions are that, in the case of a published work, the work is first published within

the parts of His Majesty's Dominions to which the Act applies. Or, if the work is not published, that the author, when he made the work, was either a British subject or resident within those parts of His Majesty's Dominions to which the Act applies.

There is really no material difference between this provision and that embodied in the 1862 Act, nor did the question of registration make any material difference except in the greater facility already mentioned. Under the present Act, in any action which is taken for infringement, it is presumed that the work is one in which there is copyright, and it is further presumed by the Court that the plaintiff is the owner of the copyright; it is left to the defendant to show that he isn't. The position is therefore scarcely to be distinguished from that under the 1862 Act, because, although photographs could be registered, no inquiry was made by the registration office to ascertain whether the persons registering copyrights there had in fact a legal title to such copyrights. The legality or otherwise of their titles was a question reserved for the Courts. Therefore the difference between the 1862 Act and the present one in this respect consists simply in the presumption that in the general way a person would not register a photograph at Stationers' Hall unless he possessed, or honestly thought he possessed, the copyright in it. Under both the 1862 and the present Act his title to the copyright was and is a matter to be settled by the evidence brought by parties in a legal action.

Now, that ought to be quite clear—viz., that copyright in a work made under one or other of the above-mentioned conditions is an asset or property which can be transferred from one person to another. Section 1, however, does not say anything as to the ownership of copyright thus created. This is done in Section 5, which sets it forth that the author of a work is the first owner of copyright therein. With certain vital reservations, however. Inasmuch as these latter were derived in a large measure from the 1862 Act they are fairly familiar to photographers. It is, we suppose, fairly well realised that copyright in a photograph made by a photographer to the order of somebody else or by a photographer in the regular paid service of somebody else belongs to that somebody else. There is no need therefore to stress the importance which these qualifications have in determining the ownership of copyright; they are, we believe, now universally familiar to photographers. Yet there are, unfortunately, cases which present difficulty in the way of saying whether the photographer actually does or does not come within the scope of one or other of these relations to a "somebody else." That is to say, it is often doubtful if he is carrying out the order of somebody else and being paid for it, and equally whether he is in the paid employment of a somebody else in respect to the making of some particular photographs. It may therefore be of service if we endeavour to throw some light on cases of this character which may crop up.

A case which very commonly leads to dispute is that in which a photographer obtains permission to make a photograph of a group of members of some club or society, very often under some loose verbal arrangement that the club may purchase copies, but without it being specifically defined that the club is ordering the photographer to do the work and is liable for the payment for it. Another kind

of case is that of a photographer forming one of an exploration party, but not specifically paid for his photographic services. A dispute may arise as to whether the party as a whole is the owner of the copyrights in photographs taken, or whether these are the sole property of the photographer. Still another instance of this kind is that in which a photographer obtains some kind of privilege for the making of certain photographs which he wants to take—a privilege, for example, such as advance admission to an exhibition. In a case such as this, as also in that of an exploration party, there may be even an arrangement according to which the person granting the privilege or the members of the party as a single body agree to take a proportion of the profits which the photographer makes from his work.

Now, in cases such as these the 1911 Act is fortunately much more definite than that of 1862 in specifying the conditions which require to be fulfilled in determining the ownership of the copyright by the photographer or by a "somebody else." Section 5 of the Act says that the photograph is the photographer's copyright unless it "was ordered by some other person and was made for valuable consideration in pursuance of that order," and, moreover, was made in the absence of any agreement to the contrary. In cases of the kind we have instanced there is usually no order, no person or body who can be sued in a county court in respect to payment for the photographs, which the photographer has made; and this latter is a test which can usefully be made in seeking to determine, in the photographer's own mind, whether an order was or was not given. In a case such as that of the member of an exploration party, the terms of his engagement require to show that he is in regular paid service for his photographic work if it is desired to sustain the ownership by the party as a whole of the copyright in photographs which he takes. In the case of a photographer who grants a proportion of his profits in return for some privilege, it is, we think, perfectly clear that the consideration is from the photographer to the person granting the privilege, and not the other way about, for which reason it follows, of course, that the copyrights in any photographs which the photographer makes belong to him. Those who take the contrary view, namely, that the photographer received a certain valuable consideration in the shape of the privilege granted to him, and that, therefore, the copyright belongs to the person who granted the privilege—those who take this view can base it only on the judgment in the case of *Stackemann v. Paton* given under the 1862 Act. But, as we have pointed out several times, the incidence of this judgment to cases such as these disappears under the present Act in view of the specific terms of Section 5 to the effect that the work must be both ordered by some other person and made for valuable consideration in pursuance of that order. In *Stackemann v. Paton* the photographer's work was certainly not "ordered," and moreover Mr. Justice Farwell in his judgment meticulously distinguished between a "good" consideration, which he regarded the photographer as having received, and a "valuable" consideration, which, under the present Act, is the only kind of consideration which the maker of a work must receive in order to deprive him of copyright in it.

FORTHCOMING EXHIBITIONS.

October 13 to November 29.—Royal Photographic Society.—Secretary, J. McIntosh, 35, Russell Square, W.C.1.

November 12 to 15.—Rotherham Photographic Society. Entries close November 3. Hon. Sec., C. Robinson, 26, Broom Grove, Rotherham

November 20 to 22.—Nottingham and Notts. Photographic Society. Entries close November 8. Hon. Sec., A. Beeston, 103, Nottingham Road, Nottingham.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Entries close December 1. Sec.: John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION

A PERSONAL IMPRESSION BY F. C. TILNEY.

THERE cannot be said to be many ways in which the annual display at Russell Square has an advantage over that of the London Salon at Pall Mall. But in one respect the older institution has a boast to itself; for it can point to a sign of development on its own walls which does, in truth, mark a new phase. There are a few oil and Bromoil transfers which, if I may be allowed to say so, reach to a height of style that surpasses what has been done hitherto in any medium of which photography is the basis. They are by Fred Judge.

The Kodak Company having offered to give a demonstration of advancement of photography on artistic lines that these times are blessed with. He has carried printing in colour further than most towards a possible goal. His commercial work, with all its mannerisms and drawbacks, has set a fashion in topographical postcards. But his little set of prints over the mantel-piece of the Meeting Room in Russell Square surpasses all previous efforts, and prove him to be possessed of that rare sense of style which is about the last thing to come to pictorial photographers. These little pictures have a quality that is found in delicate drawings, in mezzo-tints, in steel-engravings, and in lithographs; yet they resemble none of these things. They are, in fact, the achievement of what we have all been hoping and looking for for years. They are photographic and yet they are without the hopelessness which is the skeleton in the cupboard of pictorial photography. It is easy to imagine that prints made in this manner may become individually precious things coveted by the collector.

Much of this value is, of course, the outcome of the taste and skill of their author; and in that respect they have had, and have to-day, their equal in the works of scores of other workers. But it is in the fact of their rendering the customary excellencies of good pictorialism in such an alluring, personal, and amenable medium as Mr. Judge has perfected that their great claim rests. If the Society of Painter-Etchers were to hang "Approaching Storm" (73) or "Kent Oast Houses" (75) in one of its exhibitions, it is certain that either would win high praise in that august assembly of work in the finest traditions of graphic art.

Is this not what our photographic amateurs have been striving for all these years? Demachy, it is true, made a reputation for photography on these lines years ago; but his works have remained all but unique. His mantle fell upon a very few. Mr. Judge wore it first at the Camera Club. It is to be hoped he will wear it at all times and uphold the fashion for it amongst our camera artists.

Mr. Judge's transfers are bright, delicate and rich. They have that fine granulation which the mechanical smoothness of photographic tone makes us regard as a long-awaited liberation. Being clear of photographic material, their high lights are clean—pure paper, in fact, where necessary; whilst their tones, being pigment and not a chemical darkening, are capable of the deepest and richest shade of black where necessary. Add to this that their permanence is that of the indestructibility of the pigment and the paper, then there remains but one possibility for dissatisfaction in them, and that does but lie in the artistic shortcomings possible to all kinds of art expression.

But such shortcomings are few. Perhaps "Sussex" (71) is a little too full of material. It wants quietening, at any rate. The oast-houses in the mid-distance are really subject enough in themselves, and the buildings and incidents on the left of the print might either have been suppressed or eliminated with advantage. The other prints call for no such criticism. "Approaching Storm" (73) is a little masterpiece

with the characteristics of a mezzotint. "Kent Oast Houses" (75) reveals what effective extremes of light and shade the process is capable of, without loss of homogeneity. The buildings shining in the sunlight of the middle distance are seen beyond a sort of open shelter in the shadow of the foreground. This arrangement supplies an admirable design exactly in the style of the drawings and etchings of old. "Pastures by the Sea" (77) is much simpler in composition, but its feeling and quality lack nothing. In "Gourock" (79) the smoke from a manufacturing town in the far distance has given a choice theme, of which Mr. Judge has taken skillful advantage. It is obvious from the repeated merits of these prints that they owe nothing to happy chance, but are the actual results of artistic thought and feeling.

Another excellent feature of the exhibition is the work of Bertram Cox, and chiefly his imposing picture of a ruined mill, to which he gives the title, "Four Square to All the Winds that Blow" (105). This is a Bromoil print, worked with due regard to fine pictorial traditions. Its design is admirable, and the treatment of light and shade shows how intensely its author has felt the sentiment of his subject. Mr. Cox's other works are rather discounted by the success of his mill; yet if that were not there, they would be appraised as among the best in the collection. "The Bail, Lincoln, by Night" (59) has a fine and convincingly true effect. The old houses lose their outlines in the night sky, but gleam gently in the faint light of the street. The windows that are lit from within are managed with reticence and loyalty to accurate observation. It is easy to vulgarise such a theme as this, but here all is in perfect keeping. "Gawsworth Common" (84) is an open landscape of excellent composition. Perhaps the sky lacks a full measure of luminosity, but the whole thing is beautifully felt. A somewhat heavy sky is likewise a misfortune in the otherwise satisfactory "Runton Gap" (104), a cliff scene, and the only one of Mr. Cox's set which, by its necessarily high horizon due to an elevated standpoint, bears the characteristics of photographic selection.

It has been my ill-fortune to rail against camera-picture skies for many years; and although progress is slow, yet there does seem to be evidence that photographers are at last waking up to the fact that to put some sort of cloud forms into pictures is not necessarily to achieve a sky. Recent discussion on the matter has elicited a few signs that photographers are beginning to understand that, cloud forms or none, the sky must be luminous. It is better still to meet prints which support the contention. Thos. Bell's "Sussex" (53) is one of these, and it has the further merits of possessing atmosphere. Its effect is very tenderly given upon a composition of simple lines. Good in another direction is the highly dramatic mountain and lake scene by Mr. L. J. Steele, "The Squall" (67). Here the sky is not luminous because it is heavily overcast, but it is well conceived and skilfully presented. J. W. Haynes, however, in "The White Cottage" (101) has a sky of remarkable luminosity, only he has achieved it at the expense of the tones of the other parts which have been a little falsified. The effect of late evening is well and truly given in "Nocturne" (106), by Herbert Felton. He has not done better in his other works. A charming quality distinguishes the "Landscape" (98) of Richard Hopkins, who has managed, in his clean and even tones, to get a painter-like look into the simple and expressive lines of his composition. It is a picture with a perfect mood of a quiet, cloudy day in a stretch of open country. The sky

is beautifully rendered, and its clouds are photographed, not "brought up by hand." This is one of the gems of the show in my view, and proves what is possible in a subject the chief feature of which is its great simplicity of material. There is one more good and expressive sky in "The Storm" (113), by Mr. and Mrs. C. S. Ferguson, with a foaming sea beyond a dark headland.

A remarkably fine design and effect is given by Thos. Bell in his "On the Thames" (64). It is a masterly treatment of an oft-attempted theme of the river and St. Paul's in the distance—a charming mist picture. There are two other works so similar in subject as to form an instructive comparison. One is "Isleworth" (14), by M. O. Dell, and the other, "Dawn—Sun Rising through Mist" (17), by Lionel Wood. The first is a very pictorial effort, its reeds in the foreground and its general composition, together with its misty effect, constituting a most acceptable effort in picture-making. But the sun and its broken reflections in the river do not carry conviction. If they are "faked," the business has been very well done, though not quite well enough. In the case of "Dawn," the composition is scattered, and the pictorial effect spotty; but the sun and its reflections strike one as true. Here, then, is a contrast in methods and results. If one could take Mr. Wood's sun and its reflected image and substitute it for Mr. Dell's hard disc and stripy reflections in "Isleworth" we should have a picture of complete satisfaction. Mr. Dell's "Ranmore Common" (50) also has much in common with C. P. Crowther's "Early Morning, Lincoln's Inn Fields" (52). Both depict the rays of the sun shooting through the leaves of trees; but in this case there is not much to choose between the prints for merit, for each one gives with splendid effect a very fascinating phenomenon.

H. van Wadenoyen, jun., has made a signal success of his "Moonlight" (60), where some old houses are finely and

broadly treated in light and shade. The moonlight is quite convincing, and this is in no way due to the green tint of the print. Green for moonlight is a convention of the stage and the cinema. Moonlight has a warm tint in reality, but, of course, a warm-tinted print would lack the suggestive "label," and would look like the ordinary daylight of the average print.

The Bromoils of G. Bellamy Clifton get better and better. His views of Oxford are as good as anything he has yet given us. Perhaps the best is "A By-way in Oxford" (89). Architecture is not plentiful here, but what there is of it is remarkably good. H. E. Wood's "Hallowed Walls" (45) shows a clever treatment of the lines of the steps of a porch of St. Paul's to make an effective design. A street scene of great beauty and interest has been sent by Mr. and Mrs. F. Weston. Its title is "Chinatown" (24). How a picture of such well-rendered planes, so fine a light effect, and such happy design could have been hung on the worst wall of the room is a thing beyond comprehension. "In the Court of Columans" (58) is a purely architectural subject by W. G. Shields. Its light and shade is very pronounced and it looks rich and strong, but it is really too full of matter, and wants the repose of an open space. Herbert Young's "Ruines de St. Césaire le Vieux" (74) is also a fine work.

A few other architectural themes by W. Wilson Smith will commend themselves to the visitor, notably "Backwater at Bruges" (44), where the effect of contrast is excellent.

There are some woodland subjects of good feeling by H. Y. Simmonds, Wm. Rawlings, T. H. B. Scott (and his are strong in mood), Floyd Vail, and others.

It is, of course, ungracious to complain of the poor lighting of these rooms, but it does seem a pity that so much good work should be discounted by being shown at a disadvantage.

F. C. TILNEY.

PRACTICUS IN THE STUDIO.

{Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Painting Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).

Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).
Apparatus Repairs and Renovations (July 18).
Posing the Head (July 25).
Intensifying Portrait Negatives (Aug. 1).
Workshop Jobs (August 8).
The Personal Factor (Aug. 15).
The Keeping of Negatives (Aug. 22).
Reduction of Negatives and Prints (Aug. 29).
Leaky Roofs (Sept. 5).
Blinds and Curtains (Sept. 12).
Miniatures (Sept. 19).
Printing Portrait Negatives (Sept. 26).
Wedding Groups (Oct. 3).
Combination Printing (Oct. 10).
Flashlight Work (Oct. 17).

FLASHLIGHT PORTRAITURE.

HAVING dealt with the character of the flash and the influence of distance and position upon the lighting of the sitter, I will this week go more fully into the details of portraiture by this light. If anything at all approaching ordinary studio

lighting is aimed at, the unshielded flash must never be employed; that is to say, a diffusing screen, which may be of paper, calico, tracing cloth, or ground glass, must be interposed between the light and the sitter. Behind the flash

there should be a white reflector, and this may, with advantage, be larger than the diffuser, the light from the uncovered margins helping materially to shorten the exposure.

The position for the lamp must be carefully chosen, and this is not a difficult task for anyone who really understands daylight work. Less experienced operators will do well to experiment with a good oil lamp which can be moved about by an assistant while the operator studies the effect on the face, from a position behind the camera. When the lighting is deemed to be satisfactory, the support for the flash lamp should be placed so that the flash, when fired, should occupy the same position as the lamp, not forgetting that the flash is of much larger area than the lamp flame, and that the centre of the blaze should occupy the same position as the centre of the flame. The room or studio should be lighted as brightly as possible, before and during the time that the flash is being fired, as this not only makes the flash less disturbing to the sitter, but keeps the iris of the eye at its usual diameter. When a person has been sitting in a dimly lighted place, the pupil of the eye increases in size, and this is shown in a flashlight portrait, since the period of exposure is too brief for it to contract to its normal diameter.

For two reasons it is desirable to have the sitter as near to the lamp as may be comfortable to him. One is that, less powder being needed, expense is saved; the other is that the smaller the quantity of powder used, the shorter is the duration of the flash, so that there is less chance of movement either of the eyelids or the head. Another advantage is that there is less smoke. Flash powders vary in their smoke-generating powers, but I have never found one which by any stretch of imagination could be described as "smokeless," which is claimed to be a characteristic of some of the commercial powders. We have, therefore, always the smoke to dispose of. Where only an occasional exposure is made, it may be allowed to disperse naturally by opening windows or doors, as may be necessary. When a number of exposures have to be made in quick succession, the smoke must never be allowed to enter the room, as a very small quantity will destroy the brilliancy of all negatives exposed after the first one. To avoid this, the flash should be fired in a closed chamber with a wide chimney or other outlet communicating with the outer air. A good many years ago I used a very effective lantern, made of sheet iron. The front was composed of a sheet of ground glass, three feet square; the depth from front to back was about eighteen inches, and four simple blow-through lamps were fitted inside. This was hinged to the studio wall, so that it could be swung out at an angle to give a little more frontlight. A small door in the side allowed the lamps to be re-charged with very little trouble. The chimney, which was about six inches in diameter, passed through the studio wall and was covered with a cowl to prevent the access of rain and to obviate a down draught. This arrangement was quite satisfactory, and the portraits could not be distinguished from those taken by electric or even daylight. When using such a fixed lantern it is a good plan to fix three or four incandescent gas lights at the edges of the ground glass. These serve to focus by, and give a very fair idea of the lighting which will result from any alteration of the position of the sitter. A cheaper form of lantern may be made of thin wood thickly coated inside and out with whitewash, the front being made of nainsook, fireproofed with the usual solution of tungstate of soda.

With such lanterns either the explosive flash powders or pure magnesium powder may be used. The former give a quicker and more actinic flash, but they require care in using and should not be trusted in the hands of young or inexperienced assistants, the principal danger being that of premature explosion when used in lamps which require mechanically struck matches, detonators, or the "flint" and wheel. If the trigger

is accidentally released while the powder is being placed in the tray, loss of eyesight or, at all events, severe burns may easily result. Having pointed out the risk, it is only fair to say that I have used such powders ever since their introduction without having met with any mishap. A very safe and convenient method of ignition is to place a very small tuft of gun cotton partly under the powder, and to apply a lighted taper to this. The procedure it will be seen is exactly the same as with touch-paper, with the difference that the explosion occurs immediately and not after an interval of several seconds, as with the touch-paper. Electrical ignition has often been recommended, but it is too troublesome for most people, and is not always certain in action. One appliance sold by Boots answers very well. In this a current of 4 volts from a fresh pocket-lamp battery is used to ignite a small fuse somewhat like an ordinary match. The fuses must be fairly fresh and the battery in good order to ensure certainty of firing.

Flash powders are usually sold unmixed—that is to say, the magnesium in one tin or bottle, and the chlorate, nitrate, or whatever the remaining compound may be, in another. Only sufficient for a few days' use should be mixed, as, although the mixture will explode after having been made for several months, its actinic value is greatly decreased when compared with a freshly mixed sample.

Pure magnesium powder is perfectly efficient in action, but makes more smoke and requires a spirit or gas flame to ensure combustion. If burnt in a properly constructed lamp it is quite safe, the only danger being that of sucking back the flame into any closed receptacle holding the powder. Several good lamps are to be had from the dealers, and some of them can be used on groups, one large pneumatic bulb serving to project the powder from several nozzles. I have done very satisfactory work with the pure magnesium, and can strongly recommend it for studio work where a fixed installation is possible. One of the best-known flashlight workers, Mr. Fradelle, would never use explosive mixtures, and his work certainly did not suffer in consequence. Magnesium is very subject to oxidation of the surface, and should always be kept in tightly-corked boxes or tins, as it is difficult to secure perfect combustion unless the powder has a silvery brightness.

The metal may also be burned in the form of ribbon, and this is sometimes useful on outdoor jobs where a flash is objected to. No apparatus is necessary except a box of wax matches and a pair of pincers or even a paper-clip to hold the strands while burning. About a yard of ribbon is necessary to illuminate an office or small workroom, and I have found it convenient to plait four strands together to make a torch nine inches long. The ribbon must be quite bright, or it is liable to go out before the length is consumed, a rub between a folded slip of sand-paper will soon remove any oxide and leave the ribbon in good burning condition. As the burning ash is liable to drop, an old tray or piece of old carpet should be placed to receive it and prevent injury to the floor or carpet. I always make a point of carrying a coil of magnesium ribbon in the camera case when on outdoor work, as it will often enable an otherwise impossible interior to be taken successfully.

Some years ago the Platinotype Company introduced an apparatus for burning the ribbon in a globe filled with oxygen. This system gives a very actinic light, but unfortunately it was rather a clumsy affair, and since the general adoption of electric lighting we have heard little of it. Some of the best portrait work by magnesium which I have ever seen was made by this method.

Although I have spoken only of magnesium, I must not omit to mention that aluminium answers the same purpose, and is, or has been, used in some of the commercial flash powders. Aluminium foil burned in oxygen gives an even more actinic flame than magnesium, but in the pure powder form is rather more difficult of combustion.

PRACTICUS.

THE ART OF NEGATIVE MAKING.

SOME few weeks ago an advertisement appeared in these pages for a "negative maker." Without asserting that such an advertisement never appeared before or since, as a cover-to-cover reader of photographic literature I have only seen the one, and in a long and chequered career have only met three craftsmen whose work consisted purely and simply of negative making. And yet in the quality of the negative lies the secret of good photography and on the making of it hangs the smooth running of much of the after-work.

A fellow "pro." once remarked to me that the customer did not see the negatives, and so if the prints were all right nothing further mattered. I pointed out that customers don't usually see beyond the reception-room and studio, but that was no argument for a cramped or leaky dark-room.

Bad negatives are discouraging in their very appearance. They increase the labour of retouching, they use up the printers' time and temper, and they waste paper and developer. And there are more bad negatives made than good ones. I might go further and say that a really good negative—a negative that strikes expert and tyro as decidedly good at a glance—is exceptional.

Now the making of a good, an undeniably good, negative is by no means a difficult process. It requires neither genius nor luck, for before the days of tank development, artificial light, and plates of the high-velocity type, good negatives were common. Anyone who has seen and handled professional negatives of thirty years back will endorse this.

It would seem, therefore, that slow plates, dubious daylight, and cumbersome methods of development are necessary for good results, while tanks, half-watt lamps, and fast plates are responsible for the unreliable negatives that most printers know only too well. Slow plates certainly have advantages that are not universally recognised, and the desire for "speed" is responsible for much poor work, but good negatives can be made on any plates more easily by modern methods than by the laborious means that the old school was dependent on. It is only necessary to give the modern methods a fair chance and not to expect impossibilities to see how much superior they are in every way.

The beautiful negatives of thirty years ago were—many of them—made in spite of the prevailing conditions: they simply had to be good, for any imperfections would be faithfully reproduced in the prints. Just as there were no fast plates or electric light to overcome dark days, so also there were no extreme grades of papers to "cover up" faulty negatives. The advantages possessed by the modern photographer should mean improved negatives, but they offer a clue as to why the improvement is exceptional rather than the rule. Under the old conditions it was imperative to take negative-making seriously. A badly exposed or wrongly developed plate was equivalent to a re-sitting. Negatives that were impossible in appearance were usually considered impossible for printing, hence they were discouraged. With present-day methods the same anxiety is not necessary, but no methods are entirely automatic and a modicum of care is essential with any methods to ensure correct results.

A perfect negative might be described as one of a well lit subject which had been correctly exposed and developed. Lighting is, of course, an artistic function, and as every artist has individual ideas (without which there would be no art) I will pass over lighting with a solitary hint. When the required effect is difficult to get, owing apparently to sheer cussedness on the part of the daylight, it is sometimes useful to photograph a white background—making sure it is white, no mixed tints or uneven patches—with a very short exposure, the lighting being arranged as evenly as possible. Any unsuspected unevenness in the light will show up surprisingly on the negative, and by its aid can be traced and remedied.

Daylight exposures are generally reckoned by the process of mentally "reading" the light, a practice which requires much experience to become expert at. Approximately correct exposures for any time, any weather, can be calculated with the assistance of one of the many exposure reckoners on the market. True, these reckoners do not include a section for studio work, but the exposures advised for "indoor portraiture" divided by some particular factor will be found suitable. The factor can be found by experiment. For instance, suppose 6 seconds is advised at $f/8$ with such and such a plate under such and such conditions, and 2 seconds is found to be correct by experiment in the studio under identical conditions, then all calculations from the reckoner should be divided by 3.

Artificial-light exposures are less variable and can be kept well in hand by the occasional use of an experimental plate. It should be remembered, however, that an exposure that is correct for a full length "sketch" of a lady in white is not sufficient for a black coated bust against a dark ground.

Tank development is a process that makes us wonder what we did without it. The development of a couple of hundred plates is now a vastly different thing from what it was, and the ease with which plates can be put through is no small consideration, particularly when no risk of bad results is entailed. If the important details of tank work are neglected, however, there is a big risk.

The details I refer to are accurate compounding of the developer, thorough mixing and careful dilution, time, and, last but certainly not least, temperature. To take them in the reverse order, temperature is more likely to trip up a careless worker than anything else. I remember once asking an operator why he did not use a thermometer. He replied that the hot water he used to dissolve his sulphite "just brought the tank up to the mark." This occurred on a frosty night. The following August he was still proceeding on the same lines, oblivious to the fact that "the mark" had risen some thirty odd degrees.

A slight mistake in time is not so serious, but it is very little trouble to keep both time and temperature exact.

Developing formulae and dilution are matters of individual choice; any developer at any strength in reason will produce fine negatives if used deliberately and with intelligence.

Negative making is considered by some as ended with the fixing. Others include reduction and intensification, while others bring in retouching and other artistic or mechanical treatment. To go into them all would be too lengthy, but a passing word on each will not be out of place.

Reduction of harsh negatives is often carried out with Farmer's formula when the correct thing would be persulphate. The reason for this is probably that persulphate needs a little coaxing; sometimes it seems to hang back, sometimes it needs acidulating. Intensification still goes on with mercury-ammonia in spite of all that has been said and written on the advantages of bichromate. For those who haven't bichromate handy, mercuric iodide is far superior to the chloride and much simpler and safer. It consists of one solution only, it does not demand careful washing out of hypo, it seldom stains, and, besides being a useful intensifier, it will also detect improper fixation by whitening any invisible silver thiosulphate which can then be fixed out by re-immersion in hypo.

Leaving retouching alone as far as these remarks are concerned, I would still like to point out that where an aerograph is handy it can be turned to distinct advantage on certain negatives. Copy negatives can be vignettted and sketchy backgrounds strengthened with an aerograph in as many seconds as it would take minutes by any other means. For this work red dye is preferable to paint, though it has the disadvantage that it will not rub off if required.

THEMIST.

PHOTOGRAPHS OF GEORGE ELIOT COUNTRY.—At a special meeting last week at the premises of the Coventry Photographic Club the collection of photographs illustrating scenes in the life and writings of George Eliot were formally handed over to Mr. E. A. Savage, librarian of the Coventry City Library. The photographs number from sixty to seventy, and had been prepared as a contribution in

connection with the recent celebrations of the centenary of George Eliot. Mr. Savage, in acknowledging the donation from the Coventry Camera Club, said that it should be a matter for congratulation that Coventry now possesses the finest and most complete photographic record of George Eliot in this country. The photographs are to be displayed as a public exhibition during November.

SOME SUGGESTIONS ON PHOTOGRAPHS OF TILE WORK.

[We are glad of the opportunity of reprinting through our contemporary, "American Photography," the following notes which form a booklet issued by the Associated Tile Manufacturers of the United States specially in reference to the conditions which require to be observed in making commercially valuable photographs of rooms and places for the floors and walls of which tiles are used. It would seem that the notes have been drawn up for the information of individual tile manufacturers. At any rate, they exhibit such an informed sense of what is required in photographs, not only of these subjects, but of commercial subjects in general, that they deserve the widest publicity which can be given to them among photographers.—EDS.—"B. J."]

I.

THE value of a photograph as an instrument of tile promotion work rests with three salient necessities. First, and above all, the photograph should show a good tile job, something readily recognised. Secondly, it should have artistic, that is to say, pictorial qualities. Thirdly, it should possess that degree of technical excellence, finish, tone, etc., which distinguishes the serious work of expert photographers and specialists from the nondescript perpetrations of the dilettante.

The first requirement has proved a reef on which many a boat has been wrecked, for the most thoroughly trained and high-priced photographer cannot efface the setter's and designer's sins. Few serious attempts have been observed that wholly satisfy the second requirement, and only in rare cases have discrimination and care been exercised to make certain of the third.

We shall therefore pass in review those essential factors which tend to bring about or enter into the production of good photographs without, however, venturing into a boundless jungle of unnecessary detail.

Always we must hold in mind that to us any photograph is a means to an end; its sole object is to set forth effectively and convincingly the practical worth and artistic merit of tile. Every effort should be put forth, every device employed, and every principle of good taste applied to depict tile and tile work to the most telling advantage.

Considering the undeniable value of pictures as sales mediums and the lasting impression they leave on the mind, the production of photographs of tile work should not be left to luck or chance. A range of important requisites must be fulfilled, else the result will defeat all efforts to interest, enthuse, and convince a prospective user of tile.

A mere picture cannot fill the bill. A poor photograph is worse than none. Only by careful selection of subject, good photography, and premeditation of effects can a picture of lasting value as a sales medium be evolved.

All of our photographs must cater to the inherent love of mankind for the beautiful, no matter how practical a subject they depict. Along the lines of this fundamental human trait our appeal can be made with least resistance. The charm of a beautiful picture arouses the esthetic sense and excites an impulsive desire for possession. In this way the picture of an exquisite kitchen or bathroom causes admiration—a sort of pleasure—that tends to create a want, an ostensible need, for a similarly attractive kitchen or bathroom. The tile contractor eventually participates in that pleasure.

The initial step is the selection of the proper kind of a job. Jobs of appeal and in harmony with the sentiments of everybody constitute the most desirable subjects. Consider the sentiments of people in general and avoid as much as possible tile work installed in close proximity to water-closets, urinals, and similar places. To picture such spots with delicacy requires unusual skill, and had better not be attempted.

Naturally, the next step to consider is the workmanship of the job to be photographed. Workmanship is a complex topic when it comes to tile work, and to define its consummate meaning shall not be attempted here. The tile contractor himself, better than anyone else, knows the axioms of good workmanship. While there are any number of intermediate degrees of excellence, it should not be difficult to distinguish between an actually good job and a poor one. However, pay especial attention to careful lay-out and fitting of tiles into given spaces, to uniformity, neatness, and geometrical accuracy. Avoid jobs sprinkled with "dutchmen." Incorrect use of trim shapes is also a defect.

The design is one of the first things we notice in a photograph. Let this first impression be pleasing.

By design is meant that part of the tile work which deals with deliberate planning and arrangement. It has to do with the execution of an idea, an inspiration, that arises out of the conditions peculiar to each job.

Appropriateness, utility, and delight are the ultimate objects of design. Good design is therefore a relative term, but no tile job can be called "good" unless the design also deserves the attribute "good."

A design can be original, elaborate, decorative, stunning, striking or symbolic without being artistic—without being tasteful, beautiful, pleasing, and fitting. In spite of the former characteristics, it may be crude, commonplace, irritating, or unsuited. There can be too much or too little—too large or too small, too light or too heavy design.

There is no basis for the current presumption that a design must of necessity be in colours. Any white wall, for instance, may be the object of good design, and pleasing effects produced in monochrome by variety and rhythm in size, shape, and direction of units in combination with the joints make excellent photographs.

In all cases it becomes a matter of good taste and judgment to decide between desirable and unsuitable jobs for our purpose.

After a number of jobs have been selected arises the problem of finding a capable photographer. A man who has had experience in architectural or commercial work should be secured, an expert with wider knowledge than that of mere mechanism and chemical details; he should be able to submit satisfactory samples. There is more in real photography than just pressing the bulb. As there exists a vast difference between tile contractors and tile contractors, so is there an equally deep gap between photographers. The mere fact that a photographer charges a high price for his work is no indication of great ability nor value in his work.

A few "Don'ts" may not be out of place in this connection:—

1. Don't try to take pictures of tile work yourself.
2. Don't think any portrait photographer can do it.
3. Don't give the work to the lowest-priced man on account of cheapness; it is poor economy.
4. Don't leave everything to the judgment of the photographer.

No matter how "good" a photographer is engaged, it is advisable to go over the ground with him, give him instructions in regard to the part to be photographed, point out any important or peculiar features, things that should be brought out or those to be omitted or subdued. It will help him considerably to know what the essentials and peculiarities of tile work are. Also, a few pencil strokes will often indicate to him what is wanted much better and quicker than the most careful verbal instructions. A good photographer and a good tile man make an excellent team.

Much depends on the selection of an advantageous view-point, or, in other words, where to set up the camera. The more care the photographer exercises in determining this point, the more surely can a satisfactory result be expected.

Assuming for the time that the entire room is tiled uniformly, the location of this point is influenced by various factors: location of the windows or other sources of illumination and the resulting distribution of light and shade; extent of the subject to be photographed as to width and height; the lens of the camera; by the foreground and middle distance; the equipment or furnishings, the nature of the design, and similar conditions.

Photography is impossible without light. Yet, in the photograph, shade is as necessary as light. But shade should never be so impenetrable nor light so bright that details are lost entirely. The illumination must be of such character "that the parts represented in shadow shall still have the clearness and warmth of those in light, and those in light the depth and softness of those in shadow."

This can be controlled to a greater extent than seems possible at first thought. In most cases the desired illumination may be obtained by watching and waiting till the best natural lighting conditions occur. Watch for that time of day when the particular portion of the tile work to be photographed is illuminated to the best advantage, which may be in the early morning, at noon, or late in the afternoon.

On the other hand, some subjects never receive adequate or suitable illumination naturally, and in such cases artificial light must be resorted to.

Sunlight—of all sources of light—is the strongest, not only in regard to brightness, but also in respect to chemical action on the sensitised photographic plate; and, by the way, it is the cheapest. Keep in mind that detail is lost in extremely bright light and very dark shade; that the brighter the source of light, the stronger the contrast between light and dark portions of the pictures and the sharper the edges of shadows. Excessive intensity can be reduced by putting white or light blue tissue paper over all or some of the windows, over the entire opening or portions of it, just as may be required to produce a specific lighting effect.

Much improvement can often be made by equalisation, especially in the upper and generally darker portions of walls, by shutting out some of the light entering through the lower panes. This will also serve to make the lighting of floors more uniform. Ordinary window blinds are usually too opaque and shut out too much light, and when drawn down over the upper panes are apt to throw the ceiling and higher portions of walls into impenetrable darkness.

White tile work looks pleasing and natural only when the photograph shows it white, not grey. Its lightest portion should be selected as subject for the picture, not the darkest. Owing to greater contrast, white tiles in a strong, bright light give snappier pictures than in diffused light, provided care is taken that reflections do not occur in the principal sections of the work.

With tile work in colours the opposite is true, and this class of work demands a soft diffused light, or the fine gradations of tone are destroyed. But even in such cases a uniformly lighted surface, without any shade whatever, is not desirable. It always looks flat and monotonous because, as has already been said, shade is as important as light in producing a pleasing picture; deep shade, however, should not occur in the main portions of the tile work or where it will detract. At least part of the tile work should receive full light, for parts in full light are usually the ones to attract the eye.

Very light subjects can be photographed also by double exposure—that is, by first exposing for one second or less in bright sunlight and using diffused light during the remainder of the necessary time of exposure.

Generally speaking, light should not come from two opposite directions, since this does away with all shade and gives a "flat" picture. In rooms having windows on opposite sides the light from one set of windows may be shut off sufficiently to allow the other set to cast some shadow. Do not shut off all the light, but use tissue paper or similar material as described above.

A certain amount of reflection is desirable, especially in white glazed work, but spotty effects should be avoided.

Flashlight rarely produces satisfactory photographs of tile work. Its manipulation is so difficult and the result so uncertain that one can never tell with any degree of certainty how the picture is going to look, because the image on the ground glass or focussing screen is observed under entirely different lighting conditions than those occurring during the flash, unless while focussing strong electric lights (without shade or reflector) are placed in exactly the same position where the flash or flashes will be fired.

The broad lights and shadows of flashlight illumination are characteristic of an unnatural absence of detail, and are always devoid of enjoyable gradations. At best, flashlight produces ghastly effects, glaring whites, impenetrable shadows, and extensive reflections. The practical deduction is this—flashlight should be used only when no other more satisfactory means of lighting can be employed. Yet a flashlight is better than no light at all.

Never fire the flash directly behind the camera when the wall is parallel to the picture plane. It will surely result in extensive and glaring reflection and increase the possibility of "fogging" the plate. To avoid danger of fire and to retain the smoke, flashlight should be fired in fireproof bags manufactured for this purpose.

Commercial photographers have perfected various methods of

artificial lighting. In one of them an electric searchlight with reflector of the order of automobile headlights is employed. The rays of light are directed over either the entire subject or dark portions during exposure. Whole rooms can thus be photographed with excellent results without the aid of any other source of light. In fact, some of the best pictures of interiors have been produced in this way, and show astonishing definition of detail. Store windows and arcades can be photographed at night in this manner. But it is also used and recommended in combination with daylight for lightening up dark portions and deep shadows. The time of exposure must then be lengthened by "stopping down" the diaphragm opening. Such apparatus must, naturally, be manipulated by a man who is familiar with its effect. Good results can be expected only where the light is moved over the subject with uniformity and in various directions—up and down, sideways and diagonally—otherwise the finished picture will show streaks and spots.

When the subject is small—as a fireplace, for instance—dark sections or corners may also be lightened up by hanging or holding sheets of paper or cloth facing such portions.

Any good photographer knows all these tricks, and they are mentioned here solely to show that a number of means and ways are available to overcome obstacles, and that lack of adequate or suitable light is no reason for giving up as hopeless the photographing of an otherwise desirable tile subject.

Anything as shining and glistening as glazed tile should convey to the mind this desirable mirror-like smoothness, polish, and brilliancy in its photographic reproductions. It cannot appear so, however, without reflections. Concrete and stone walls have no high-lights and reflections, and the mind thereby recognises their texture and identifies them. In photographs of tile work we must have high-lights and reflections or lose the key to their identification. These practical considerations are expressed for the benefit of those who anxiously strive to eliminate every trace of solar tinsel and find no rest till the last speck of warmth and joy and play of light is eradicated, with the result that tile finally looks as dead and barren as a cellar floor.

True, reflections can destroy or mar pleasing effects and can be overcome like any good thing, but as a rule such conditions can be remedied by correcting the disturbing light-effect or faulty lighting.

By faulty lighting we have reference to instances where the rays of light do not strike the tile at a proper angle. This defect can be remedied by one or a combination of "tricks of the trade." (See section on light.) Without question, some way can always be found that retains a vital amount of light for exposure and the high-lights on the tile, but at the same time eliminates extensive and disturbing reflections.

Halation is a common fault of pictures that include windows, burning lights, etc., and can seriously mar a picture. An excess of light streaming into a room through windows or radiated by powerful electric lights on the tile—especially white tile—often results in a glare and myriad of tiny reflections in different directions, and either much of the detail is obliterated or adjacent areas are reproduced much lighter than the rest. This defect can be avoided by the use of non-halation plates. Insist upon your photographer using them for all your work. Films are free from this shortcoming.

(To be concluded.)

THE CATFORD, FOREST HILL, AND SYDENHAM PHOTOGRAPHIC SOCIETY has commenced its winter session, meeting at the Dartmouth Hall, Forest Hill, every first and third Monday. A good list of lectures and other fixtures has been arranged. Anyone in the district interested in photography is invited to write to the Hon. Secretary, M. Hovenden, 18, Princethorpe Road, Sydenham, for syllabus and conditions of membership.

HORSEBACK PORTRAITS IN HYDE PARK.—According to the "Daily Mail," the Office of Works is inviting photographers to tender for the exclusive right of taking portrait photographs of persons on horseback in Hyde Park. It is stated that the period of the licence is for one year from November 1, 1919, and that the position of the operator is confined to the west end of Rotten Row on the south side, and subject to the approval of the police. Particulars and forms of tender are obtainable from the bailiff of the parks, Major W. E. C. Hussey, R.E., Office of Works, Storey's Gate, S.W.2.

AN AID TO MOUNTING AND MOUNT CUTTING.

When mounting prints, particularly those of large size where an ample margin of mount is required, it is very desirable that the side margins should be of exactly equal width. However, when a number of prints are being dealt with, the additional trouble of measuring first one side and then the other, then adjusting and measuring again, often leads to the mere guessing of the central position, with a resulting inaccuracy which may offend a more trained eye than that of the worker.

The use of a simple bisecting rule of the type illustrated and described below quite overcomes the measuring difficulty, and will be found of great assistance in rapidly centring a print on its mount.

It will be found of even greater assistance when it is desired to trim the mount of an already mounted print to fit a stock size frame, or for marking off the openings when making cut-out mounts.

The rule may be of the ordinary two-foot type, such as probably already used by the reader, but with the figuring altered so that the centre is zero and each half-inch on either side is marked as an inch in ascending order to twenty-four. The smaller divisions of quarters, eighths, and sixteenths are, of course, read as halves, quarters, and eighths with the new marking.

It will be readily understood that such a rule can be quickly placed upon a mount so that the reading is the same at both edges, after which the print can be centred on the mount in a similar manner with equal facility. From the position of the rule, as shown in fig. 1, it will be seen that the figures at the margins giving

Fig. 1.

the actual widths of print and mount respectively, any desired width of mount can be marked off when the rule is centred on the print, or any desired width of opening or space for print or tint, when the rule is centred on the mount.

There are also many other purposes in ordinary workshop or workroom practice to which this ready means of bisecting may be applied, such as marking off wood, cutting up mounting boards, spacing screw holes or halving rolls of paper.

In the re-marking of the rule the gumming of a strip of paper over the existing figures and the writing of new ones thereon is

Fig. 2.

all that is really necessary, although the method adopted by the writer will be found more effective and lasting. In this case the upper half of the rule was painted out with black varnish and, when this was quite dry, the new figures were printed in with aluminium paint, using an ordinary pen. The use of aluminium

paint in this way will be found much simpler than might be expected, and will also be found very useful for printing numbers on the backs of dark slides or titles on the covers of books. The smaller sketch (fig. 2) shows a portion of the rule when finished as above described.

VIVIAN JOHLING.

Photo-Mechanical Notes.

Detail in Coarse-screen Work.

The coarser the screen the greater the loss of detail in any reproduction, and yet very often the illustration is almost useless unless the detail is preserved. While the engraver cannot do the impossible and give detail with a coarse screen, yet it is possible with particular originals by means of a "stunt" to give the customer just what he wants. Such an original is one in which the detail is a small part of it and surrounded by work in which the detail rendering is not so important. In this case two negatives are made, one of the whole original on the coarse screen and the other of the small part showing the detail on a much finer screen. Then this part is stripped away from the coarse-screen negative, and the fine-screen negative of just that part stripped in. The engraving will print well because the fine part is supported by the surrounding coarse-screen work, but obviously the method is only suitable for special subjects.

Vignetted Half-Tones.

There is no doubt that the letterpress printer has most difficulty in printing satisfactorily half-tones with vignetted edges, and that very often the responsibility for a poor result rests upon the engraver, because he makes a vignette with edges that are too shallow. This comes about from the practice of re-etching by scrubbing the edges with a stiff brush and perchloride, which, of course, rapidly reduces the size of the dot without giving the plate corresponding depth. The best way is to paint out the plate and paint an outline beyond the vignette, and then return it to the etching bath and allow it to etch until the dot is fine as possible, which will give also the maximum depth. Or if this is considered too much trouble, and the re-etching is done on the bench, then apply the iron etch and allow it to rest on the plate without brushing, occasionally mopping it up and applying fresh etch. If a vignette that is too shallow is sent to the printer, he cannot be blamed for butchering it with a lining tool or smashing down the edges with a hammer, both of which practices are anathema to the lover of fine printing and engraving.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, September 29 to October 11:—

PRINTING.—No. 23,910. Photographic printing. F. W. Donisthorpe.

PROJECTION SCREENS.—No. 24,226. Manufacture of screens for cinematographs, etc. W. Bemrose and J. W. Verity.

CINEMATOGRAPHY.—No. 23,861. Combined reel for winding and unwinding cinematograph films on same spindle. S. England and W. Thomas.

CINEMATOGRAPHY.—No. 23,857. Motion picture machines. F. McMillan.

CINEMATOGRAPHY.—No. 24,068. Automatic fire-extinguisher and stop motion for cinematographs. W. Taylor.

COLOUR PHOTOGRAPHY.—No. 24,336. Photographic camera for taking part-negatives for pictures in natural colours. S. de Prokudine-Gorsky.

PRINTING MACHINE.—No. 24,780. Electric photographic printing or copying machines. J. B. and J. Halden and Co.

STEREOSCOPE.—No. 24,660. Folding stereoscope. J. M. Hattersley.

MOUNTS.—No. 24,756. Photo mount. G. H. Landergan.

FRAMES.—No. 24,444. Photographic frames. A. E. Phillips.

FRAMES.—No. 24,445. Photographic frames. N. Phillips.

PRINTING APPARATUS.—No. 24,598. Apparatus for photographic and mechanical, etc., printing. E. W. Spears.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ENVELOPES FOR FILMS AND PLATES.—No. 120,572 (August 29, 1917).

The invention relates to envelopes for photographic films and plates in which a sliding shutter is withdrawn for an exposure of the sensitive surface after the envelope is placed in a camera. In one such arrangement the film or plate is inserted into a bag-like sheath, which is then slid into a frame of stout paper or cardboard having a back with side and bottom edges bent over, the bottom one being bent over the side edges and adapted to engage a pro-

Fig. 1.

jecting tongue in the bottom of the camera to retain the frame in position.

The main object of the invention is to combine the special advantage of the well-known roll-film cartridge—viz., the ability of inserting the film by daylight in the developing apparatus, with the advantage which the also well-known form of packing "film-

Fig. 2.

packs" presents over the roll-film—viz., to allow the use of ground-glass in the camera, and in addition to combine these with the advantages which every single enveloping of films known up to now present over the two aforesaid—viz., that ordinary or orthochromatic films may be used at pleasure, that the plates or films in their envelopes may be sold singly and are easier transportable, and that development may be undertaken at any time without it being necessary to await the exposing of other films or to make unnecessary exposures on these only in order to be able to commence the developing, and, finally, that the films may at pleasure

be developed singly (as with film-packs, but in contrast to roll-films). Further, the invention aims at avoiding the use of an adapter (a special holder or small case for the envelope), which is as a rule used with film-packs and most of the film envelopes. The envelopes are especially intended to be placed in cameras with a hinged back frame and with a spring-mounted ground-glass frame.

The envelope consists of a back, 1, of opaque thick paper, the form and size of which will as a rule depend on the size of films, with a holding strip, 6, and a cover or shutter, 9; the two long edges, 2 and 3, of the back are bent over, and the one short edge, 4, is then bent over upon the bent edges, 2 and 3 (these bent-over portions may be fastened to each other), so that a somewhat project-

Fig. 3.

ing resilient edge, 5, is formed, and along the opposite short edge of the back plate, 1, the two edges, 2 and 3, are connected by the pasted strip, 6. Hereby an envelope is formed to receive the film-sheet, 7, which is kept in its place by the bendings, 2, 3 and 4, the strip, 6, and a bending, 8, of the remaining short edge of the back, which edge is bent under strip, 6.

Between the film, 7, and the three bendings, 2, 3 and 4, and the strip, 6 the cover or shutter, 9, may be inserted. This consists of a piece of thick paper of nearly the same breadth as the film, its one short edge having a bending, 10, which, when the cover or shutter is drawn out, will co-operate with the opposite bend, 8, on the back, and prevent the shutter from being completely drawn out. Such a shutter will ensure freedom from light-leakage during exposure.

The opposite short end of the cover or shutter has a hasp or tongue, 11, which, when the shutter is pushed down and has

Fig. 4.

covered the film, may be bent down over the rear of the back, in order to attain light-tightness, and be sealed, besides serving as a fingerhold during the withdrawing of the shutter.

When an exposure is to be made, and the lens is adjusted, the closed film-envelope is inserted into the camera. The camera may, for instance, be constructed with a hinged back-frame and the ground-glass may be yieldingly mounted therein, so that the envelope may be introduced after the back frame has been opened.

Alternatively, the camera may be constructed so that the envelope may be inserted in front of the ground-glass, while this is

Fig. 5.

pressed back. After insertion of the envelope the seal is broken, the back frame is closed if it is hinged, and the shutter, 9, is drawn up and uncovers the film, which may now be exposed. In both cases the edge, 5, will co-operate in the closed back frame of the camera with a corresponding edge, which thereby keeps the envelope fast during the drawing up of the cover plate, so that the usual manipulations for this purpose are avoided.

When the exposure has been finished the shutter is pushed back, being of stiff paper so that the exposed film is covered light-tight, and the envelope is then taken out of the camera, by causing the back frame to be opened, so that the edge, 5, is free of the corresponding edge in the camera. The envelope may then be sealed again, but in a manner which differs from the former sealing, such as by a fresh seal or by an unused portion of the gummed tongue, 11.

The bendings, 2 and 3, form a guide for the shutter during its

displacement, and owing to the bending, 4, being placed above the bendings, 2 and 3, the bending, 4, springs itself—together with the edge, 5—somewhat away from the back plate, 1, by which (when the camera is constructed in such a manner that the bending, 4, has sufficient room in it) it results that the bending, 10, slides easily in under the bending, 4, without meeting resistance, when the shutter is pushed back after the exposure is finished. The sliding of the shutter is assisted by the increased stiffness thereof obtained by the bending, 10, which serves also the task of removing, before the exposure, fluff and dust from the surface of the film, as it slides on over this when the cover or shutter is drawn up.

The hasp or tongue, 11, serves, besides for the purposes mentioned, by its tongued form, also to introduce the envelope into a developing apparatus such as described in Patent No. 119,246 ("B.J.," September 26, 1919, p. 566), and the strip, 6, serves partly as a guide for the shutter, 9, during its displacement for covering and uncovering the film, 7, partly it contributes to secure that the shutter—when the envelope is manipulated outside the camera with broken seal—shall remain in its place, protecting the film from the light, and finally it ensures by means of its thickness and by the thickenings produced on the bendings, 2 and 3, by the pasting—that the envelope remains in its place in such a developing apparatus when the shutter is drawn out in order to uncover the film for the developer.

The envelope here described may also be used for glass plates, 13, in which case two small strips, 12 (figs. 4 and 5), are then laid into the envelope along two opposite sides of it in order to keep the glass plate in its place relatively to the light-opening, as the glass plate, 13, must always be somewhat smaller than the size of the film, intended for the same picture size.

It is obvious that it is not necessary to insert and withdraw the shutter longitudinally of the envelope, but the construction may be such that the long dimension of the envelope forms the sides. Likewise the film, of course, need not fill out the whole space in the envelope, but may be smaller and surrounded by a frame which fits within the said bendings, and moreover, the invention may be varied in different ways without the principle of the invention being departed from.—Jens Peter Hansen, 10, Jacoby's Allé, Copenhagen.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

CRYSTALITE.—No. 391,510. Chemical photographic developers. Karl Malmberg, 110, Cannon Street, London, E.C.4, merchant. May 22, 1919.

LACTOID.—No. 394,292. A material manufactured from animal substances, sold in sheets, rods, and tubes, and goods manufactured therefrom. British Xylonite Company, Limited, Hale End, Chingford, London, E.4, manufacturers. August 15, 1919.

CATALOGUES AND TRADE NOTICES.

THORNTON-PICKARD ENLARGERS.—The Thornton-Pickard Company, Altrincham, have just issued a booklet describing the various models of their enlargers now obtainable. These range from the "Artist" enlarger, of comparatively simple pattern, to the "Professional" model, made only in whole-plate size, and embodying the best features of the other designs. Among these latter is the "M.C.C." No. 6, the enlarger adopted as a standard instrument by the Royal Air Force. The booklet, which contains particulars also of semi-automatic arc lamps for use in enlarging, is obtainable free on application.

ALBUMS AND MOUNTS.—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, E.C.4, send us a 32-page illustrated list of the many patterns of album for prints made and sold by themselves. A large proportion of these are of the slip-in pattern, but the list specifies also a number of designs of album in which prints are mounted in the ordinary way. The popular "Sunny Memories" series is obtainable in a considerable variety of styles and sizes, and the list also gives details of the very convenient ready-made passe-partout frames for prints of comparatively small size, which are specialties of Messrs. Butcher. The illustrations in the list fail to do justice to the very artistic appearance of these passe-partouts.

X-RAY EQUIPMENT.—Radiography is now of the highest importance, not merely in the diagnosis of disease for the purposes of the physician or surgeon, but in the investigation of industrial materials and products for flaws and defects which could be discovered so easily in no other way. A price-list commensurate with its subject has just been compiled and issued by Messrs. Watson and Sons (Electro-Medical), Limited, Sunic House, Parker Street, Kingsway, London, W.C.2. It is a book of 370 pages, and specifies most fully the items of equipment and the numerous accessories and materials employed in X ray work. A large proportion of these are manufactured by Messrs. Watson in their own workshops, but their list includes the many pieces of apparatus which owe their existence and development to experimenters in this field, the boundaries of which have been extended in many directions as the result of the great demand for X-ray investigation during the war. There can be no question that the catalogue is the most complete and up-to-date of any which those employing X-rays or interested in radio-therapeutic methods can possess. It is a large and costly book, and is supplied at the price of 7s. 6d.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, OCTOBER 27.

South London Photographic Society. "Sylvan Essex." J. McIntosh.
Dewsbury Photographic Society. "Bronni Printing." W. E. Gundill.
Willesden Photographic Society. Affiliation. "One Man" Portfolio." E. J. Steele.
Bradford Photographic Society. "Lantern Slide Making." C. E. Lawson.

TUESDAY, OCTOBER 28.

Royal Photographic Society. "The King's Highway." A. H. Blake, M.A.
Hackney Photographic Society. "Transferotype and its Uses." F. W. Slater.
Chelsea Photographic Society. Affiliation Portfolio, with criticism.
Manchester Amateur Photographic Society. "Gems of English Architecture." T. Burton.
Birmingham Photographic Society. "Photographic Technique Simplified: A Few Photographic Problems Developed and Fixed." E. A. Biermann.

WEDNESDAY, OCTOBER 29.

Croydon Camera Club. "Colour." F. C. Reynolds.
North Middlesex Photographic Society. Night Outing.
Dennistown Amateur Photographic Association. "Facts About Development." W. W. Mollison.
Partick Camera Club. "Apparatus and Exposure." A. T. Edgety.
South Suburban Photographic Society. "Picture Making in Northern Italy." G. H. Dannatt.
Royal Photographic Society. "The Late German South Sea Possessions." T. J. McMahon.

THURSDAY, OCTOBER 30.

Liverpool Amateur Photographic Association. "Aerial Photography." Lieut. Fyffe.
Rodley and District Photographic Society. Monthly Competition. "Harvesting." Hammersmith (Hampshire House) Photographic Society. "Down the Thames on a Barge." W. N. Beal.
The Camera Club. "Egyptian Jewellery." Prof. W. M. Flinders Petrie.
Richmond Camera Club. "The Engraved Works of J. M. W. Turner, R.A." Dr. C. W. Philpot.
Brighouse Photographic and Naturalist Society. "The Importance of Photography in the War." A. Dordan-Pyke.
Aston Photographic Society. "Enlarging." Mr. Leith.
Wimbledon Camera Club. "Personal Practice in Pictorial Printing." E. C. Perry.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held at 35, Russell Square, on Friday, October 10, 1919. Present: Angus Basil, Gordon Chase, A. Corbett, C. F. Dickinson, Alfred Ellis, S. H. Fry, W. E. Gray, Reg. Haines, Geo. Hana, Lang-Sims, R. N. Speaight, H. St. George, and F. G. Wakefield (London members), and Marcus Adams (Reading), F. Brown (Leicester), W. B. Chaplin (Windsor), A. H. L. Chapman (Swansea), Tom Chidley (Chester), and W. Illingworth (Northampton).

The minutes of the previous meeting were read and confirmed. Letters of regret for non-attendance were read from F. Read (Southport), and Montague Cooper (Taunton).

The Chairman offered the congratulations of his fellow members to Mr. Geo. Hana upon his recovery from a very serious illness, and expressed their pleasure at his presence once more at their deliberations. Mr. Hana thanked the members for their expression of goodwill and good wishes.

The Hon. Sec. reported that in accord with the Council's instructions he had inserted an advertisement in the "British Journal of Photography" stating that the Association required the services of a gentleman as paid secretary. He (the hon. sec.) had received

twenty-three applications for the post. As notified on the notice of agenda, these letters had been laid upon the table for an hour before the present meeting, so that every member had had the opportunity to make himself fully acquainted with the details of the applications. The Council would have now to decide what salary they were in a position to offer as remuneration, and he proposed that a small committee—a finance committee—should be appointed to make a recommendation on this point to the Council. The proposed committee might, at the same time, select the most suitable candidates, and the Council could then make a final choice.

A short discussion ensued, and Mr. R. N. Speaight moved, and it was carried unanimously, that Messrs. Corbett, Haines, Lang-Sims, St. George, Ellis, and the hon. treasurer be appointed to form the finance committee and to report to the next meeting.

The Hon. Treasurer reported that subscriptions were coming in satisfactorily, and that the number of members who had made any protest against the increase in the amount from 5s. to 10s. was negligible. As a matter of figures, less than ten members had resigned their membership out of over seven hundred payments received in the first nine months of this year. A great many more members had written congratulating the Council upon the increase of the amount, and some wishing the subscription were greater. His present position was, that he was sure of being able to present the members with a good statement of income and expenditure for the year ending 1919.

The Hon. Treasurer placed the bank pass-book on the table for inspection by the chairman, and asked the Council to authorise the drawing of cheques for accounts due to the amount of thirty-one pounds odd; agreed.

The Kodak Company having offered to give a demonstration of their Portrait films to the Council, it was suggested that the demonstration might be given as one of the features of the Congress as well as to the London members before Christmas. Some discussion arose as to the functions of the Association, and possible complaints from country members that Londoners looked after themselves first.

The hon. sec. said that he thought that the days of jealousy between London and country members had passed. Speaking for himself, he believed the Association meant to do, and was doing, all that it could do for each and all of its members, town and country alike. Nine-tenths of his work as hon. sec. was with country members, and he thought there was nothing in the point. It was resolved that the Council accept the kind offer of the Kodak Company.

The reports from members of the Council instructed to ascertain the effect of incorporation upon the future official relations of the Association with Government Departments were presented, and amounted, briefly, to a statement that the relations depended, not upon the matter of incorporation, but upon the importance of the trade interests from the national point of view, and upon the status, social and commercial, of the parties interested. The introduction or intervention of a "persona grata" was practically the only and the best method of getting into touch with officialism when such a course became advisable. The Council were fortunately in the position of having such introductions. It was pointed out that other reasons would probably operate to lead the Council to decide to become an incorporated body, notably the intended appointment of a paid secretary and the desire to limit the personal financial responsibility of the members, as well as that of the Council and officers.

Mr. St. George (President) said that the Council were indebted to Mr. Illingworth for having taken a great deal of trouble in this matter. At the present moment they had a good many "irons in the fire." He would like to see the matter of the secretaryship out of the way first. The Council agreed, *nem. con.*: That the further consideration of this matter be deferred until after the question of the employment of a paid secretary by the Council has been settled.

A complaint was made by a member that he was unable to buy roll films from the Kodak Company at trade prices. He claimed that his trade in developing and printing the film, which was strictly photographic work, was prejudiced, as customers required their cameras to be reloaded with film, which he was unable to supply, thereby losing the business of developing and printing, which was diverted to a neighbouring chemist. Members of the Council related instances of this practice working to their prejudice,

and stating that such trade regulations gave an unfair advantage to chemists and others. Mr. Chidley discussed the matter from his own experience in the matter of cameras, and stated that he should have lost the sale of a high-priced camera (Kodak) had he not been able to purchase a similar piece of apparatus for his customer from another maker. The further consideration of the complaint was adjourned.—Mr. Hana asked the hon. sec. what was the result of a somewhat similar complaint, viz., withholding goods in restraint of trade, which had come before the Council at its last sitting before the adjournment. The Hon. Sec. stated that the principle of the complaint was unsettled, but the particular complaint had been met by the wholesale house supplying the goods as required by the member.

The Hon. Sec. reported that a variety of letters and complaints had been received by him during the recess. These had all been dealt with in consultation with such members of the Council as were available at the time. The cases included claims against a railway company (put into the solicitor's hands), several cases of refusal to pay copyright fees (now collected), rights in negatives and copyrights in negatives made from aeroplanes, claims against manufacturers for overcharges, claim against vendor of a business for breach of agreement, several complaints against trade printers for non-delivery of prints and retention of the negatives, and complaints against manufacturers of dry-mounting tissue. The Hon. Sec. further reported that Mr. Arthur Broeka had informed him that there was practically no doubt that the Photographic Fair would be held at the Royal Horticultural Hall some time in April, 1920. The Congress of the Professional Photographers' Association might be therefore regarded as a certainty.

An extra meeting of the Council has been called for Thursday, October 23, to receive the report of the finance committee in the matter of the appointment of a paid secretary.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, October 21, Mr. F. F. Renwick in the chair.

The twenty-second Traile Taylor Memorial lecture was delivered by Rev. A. L. Cortie, S.J., F.R.A.S., director of the Stonyhurst College Observatory, who took as his subject "Photographic Evidence for the Formation of Stars from Nebulae."

Father Cortie did not attempt to deliver a highly technical discourse upon this branch of astro-physics to which, among other fields of astronomical research, he has devoted himself. Yet within the limits which he set himself of popular exposition he was eminently successful in bringing most vividly before his audience the lines of thought and investigation which had been followed by astronomers in dealing with the final and most elemental riddle of the universe, the formation of stars and suns from gaseous nebular material. With the aid of a magnificent series of photographs of stars and nebulae the lecturer traced the two descriptions of evidence, which gave a reasonable ground for belief that the coalescence of nebular matter into definite stellar bodies is a process which may be seen in operation. Such evidence consisted in the photograph of nebulae, and particularly those of spiral nebulae, in which the physical formation or structure of the nebulous matter shows a direct physical connection with the disposition in the heavens of luminous stars. Along the other line of investigation, that of the spectroscopic analysis of the material of nebulae and stars, the evidence in favour of the formation of the latter from the former was still more positive. Father Cortie, in dealing with this branch of his subject, showed many of the spectrum photographs of stars and nebulae made at Stonyhurst College Observatory, and pointed out how the astro-physicist was ahead of the terrestrial chemist in the discovery of new chemical elements. The spectroscopy of the stars had shown the existence of helium long before the gas was isolated in the laboratory, and there were now several elements the properties of which had been fairly well defined by spectroscopic methods, which were known to exist in stars of nebulae, but have not yet been isolated by chemists from terrestrial material. Without resorting to the expedients of picturesque illustration which are familiar to those who have heard the lectures of the late Sir Robert Ball, Father Cortie nevertheless succeeded in keeping his audience impressed, indeed overwhelmed, with the vastness of his subject, and when at last he turned for a moment to draw the inference of a beginning of

who universe, designed and regulated by something of a higher order than matter, some great spiritual power, it was felt that he had brought his discourse to a fitting conclusion.

On the proposition of Mr. D. E. Benson, seconded by Mr. E. W. Mellor, the hearty thanks of the Society were accorded to Father Cortie, and the medal struck by the Traill Taylor Memorial Committee was handed to him by the chairman for his acceptance.

The lecturer, in briefly replying, quoted, in the vernacular, some opinions of Lancashire artisans of the work of his observatory. It was evident that the astronomer-priest was a very human person.

CROYDON CAMERA CLUB.

Mr. J. Dudley Johnston gave a lecture on "Personal Practice in Lantern Slide Making," being a repetition of an exposition at the R.P.S., fully reported at the time.

The rooms were crowded, and the opinion of everybody, including the veterans, was that no finer collection of slides had ever been seen in the club. Add to this the fact that Mr. Johnston proved to be a most lucid lecturer, dealing very clearly with every step necessary to success in the most beautiful of all photographic processes, and it will be realised that lucky is the society which can prevail upon him to appear before it.

An unusual feature of the evening consisted of a strong counter-attraction in the shape of an exceedingly fair young lady visitor, who quickly absorbed the Croydon atmosphere and dry ginger-ale, and chatted in friendly fashion with one or two members in the immediate vicinity, much to the envy of those unfortunately situated in remoter spots. If ladies were permitted as members and the club included within its ranks femininity of the same order, doubtless its membership would be quadrupled in a very short time, and of an equal certainty attention directed to the lecturer would be reduced to the vanishing point.

In the discussion, Mr. H. P. C. Harpur (an expert lantern-slide maker) spoke at length and most appreciatively, but ran into more dead-ends than customary, from which he retreated with difficulty. Necessary explanations to the puzzled fair visitor that this erratic procedure merely indicated genius of a rare nature caused the gist of Mr. Harpur's remarks to escape attention and remain unrecorded. Mr. W. F. Slater struck a new note by saying that when intensifying with silver he had on occasion obtained a "Liberty" art green deposit, and a very nice colour too. A most hearty vote of thanks to the lecturer concluded a most interesting and instructive evening.

News and Notes.

HISTORIC PHOTOGRAPHS BY LORD KITCHENER.—During the past week or two there has been offered to habitués of a London thoroughfare famous for its stocks of second-hand books a volume, or album, of photographs of Palestine taken by the late Lord Kitchener in the days when he was a lieutenant in the Royal Engineers, at which time (the middle 'seventies of last century) he was an enthusiastic worker in the Holy Land. Many photographers, bibliophiles, and others who have examined the volume probably learned for the first time that Kitchener was an author and a photographer. The apparent uniqueness of the book, combined with the present-day interest in Palestine, has led the vendor to over-value his possession considerably, and to offer it at an inflated price, for the book, little known and aged as it may be, is not yet out of print; it may still be obtained from the publishers at the original price of one guinea. A correspondent who has photographed in Palestine, in sending us this item of news, further states that he has gleaned from the reports of the Palestine Exploration Society that this volume of "Photographs of Biblical Sites" was published by the Society in 1876. It contains twelve pictures taken by Kitchener during the time he was at work on the survey of Western Palestine, together with a short description of each written by himself. Some of the views taken are no longer obtainable, as new buildings of one kind or another have sprung up everywhere, altering or marred the old and historic sites. The descriptions, though very short, are charmingly written, and show what a strong feeling Lord Kitchener had for this particular part of the Near East. It appears (says our correspondent) to have been his only photographic

effort, and he took the keenest interest and pleasure in the preparation of this his only book, as his letters show, though the actual publication of it was left in Sir Walter Besant's hands, as the author returned to Palestine before it was in proof. If the negatives still exist—as in all probability they do in the wonderful archives of the Society—they should be of great value to-day, when the Holy Land and its sacred sites are attracting the attention of the whole of Christendom in a way they have never done before.

PRESENTATIONS TO A POSTAL CLUB SECRETARY.—Twenty-one years ago was established the Somerset Postal Photographic Society, and during the whole of that period the duties of Honorary Secretary have been faithfully and courteously discharged by Mr. Bernard J. Mitchell, of Frome. The members very naturally desired to show their appreciation of his excellent services, and the suggestion of Mr. A. W. Walburn, of Exeter, was adopted that a presentation album should be prepared containing from each member a print, portrait, and autograph, in addition to a silver tea service, and a gold wristlet watch for Mrs. Mitchell. It was arranged that the presentations should take place at the Salon, but owing to the railway strike postponement was necessary, and the very happy event took place at Bristol on October 15. This was the first meeting that had ever taken place in connection with the Society, the majority of the members being quite unknown to each other except through the circulating portfolios, and the gathering was, therefore, of quite a striking character. Another unique feature of the proceedings was the fact that Mr. Walburn was elected a life member of the Society—quite a new thing in postal photographic societies—and the meeting was in every way a happy and successful one.—In acknowledging the gifts, Mr. Mitchell said it was extremely difficult for him to find words carrying sufficient weight to express his feelings of thanks and appreciation of the kindly thought prompting the organisers of the presentations. The Society owed much in its early days to the kind assistance of the late Mr. Hawes, Mr. Hugh Price, of the British P.C., Mr. F. M. Sutcliffe, Mr. Barran Keene, Mr. J. T. Ashby, and several others. The membership had comprised many well-known workers—Mrs. Mary Cottam, Miss Constance Ellis, Dr. Rosenheim, Rev. Mudie Draper, Mr. S. G. Kimber, and others—who had figured at the Salon and Royal. Working the Society had been to him a labour of love, and the gifts would be treasured as long as life lasted as a reminder of the pleasure his work in the Somerset Society had afforded others during his tenure of office.—Mr. and Mrs. Mitchell afterwards entertained the members to tea. Amongst those present were members from Weston-super-Mare, Clevedon, Bristol, Newport, Risca, Hereford, Bridgewater, and Castleford, Yorks.

Correspondence.

- * * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

REVERSAL OF IMAGE IN DISH DEVELOPMENT.

To the Editors.

Sir,—Referring to this question, I also have had a curious experience. One night I was developing a roll of films (Kodak) with Certinal developer, and white light struck one end of the film. After the film was fixed I noticed that the two end exposures were positives. I wondered why. I developed another Kodak film in the same developer and towards the end of development allowed light to play on film for about a minute, still passing through the developer. Result, all positives. The exposures were all outdoor ones.

I have had reversal of the image on one or two occasions where no light has penetrated, but only within the last six months. It may be the emulsion used is different from that of last year, perhaps some improved method of Kodak's or possibly may be due to developer.

I have no facilities for going further into the matter, but these pointers may be useful to experimenters. I simply give my experience.

I noticed in a recent number a "new" method of toning with acetate of lead. I toned with acetate of lead (and it is on record in an amateur journal) twenty-five years ago. I also got good results with barium salts.—Yours faithfully,

The Huts, Victoria Falls,
Rhodesia.

PERCY M. CLARK.

STRIPPING-PLATES FOR TITLES ON NEGATIVES.

To the Editors.

Gentlemen,—With reference to your reply to "O. A." in the "British Journal" of October 17, it may be of interest to your correspondent to know that Gem stripping-plates (in lantern and "process" rapidities) are manufactured specially to provide a handy and sure method of putting titles on negatives.

A lot of titles, as you remark, may be photographed on one plate, which is developed, fixed, and dried in the usual way. A sharp pen-knife is then passed round the plate about a quarter of an inch in from the edge, and the film is detached without further treatment.—Yours faithfully,

THE GEM DRY PLATE CO., LTD.

Cricklewood, London, N.W.2, October 20.

BUYING SECOND-HAND LENSES: A CAUTION.

To the Editors.

Gentlemen,—Nowadays, when new lenses of all kinds are very expensive and somewhat rare, would-be purchasers of objectives are turning their attention to stocks held by dealers in second-hand goods, particularly pawnbrokers. For many years pawnbrokers' shops have been good places to patronise for lenses, and some very good bargains have been secured by myself and others. Most of the pawnbrokers are fully alive to the value of photographic lenses, but they, as a whole, deal fairly, and I have met with no attempts to profiteer.

Last week a small R.R. lens was purchased for 17s. 6d. (new 25s.) at a South London shop; when examined in the hand—and very closely, too—it appeared to be quite all right, and the name of a well-known London maker engraved upon the mount gave one confidence. When fitted to a camera, however, the lens failed to give any kind of image, a further examination proving that the lens had no useful focus, although the inscription cut upon the brass mount gave it as being $6\frac{1}{2}$ inches.

The makers of the lens were communicated with, and from them I learned that it was the fifth "dud" of the species they had heard about during the last week or two, all of which had been purchased from pawnbrokers. The affair at the moment is something of a mystery, and more may be heard of it later on as there are believed to be many more such lenses in the hands of London pawnbrokers.

Judging from the facts at present available, it appears that during the rush of war work—when the making of ordinary lenses was suspended and hosts of strange hands were engaged on munition work in lens factories—some dishonest workman "lifted" a few mounts bearing the name of the firm, and, knowing of the scarcity of photographic objectives, fitted into them any lenses he could find to fit, and "planted" them with pawnbrokers who, of course, had no time to try them in a camera. Purchasers of lenses from "Uncle" would therefore do well, for the time being at any rate, to pay a deposit and have the lenses on approval.—Yours faithfully,

L. T. W.

Commercial & Legal Intelligence.

NEW COMPANIES.

PEERLESS PHOTO PAPER CO., LIMITED.—This private company was registered on October 14 with a capital of £17,500 in 15,000 shares of £1 each, and 50,000 shares of 1s. each. Objects: To carry on the business of manufacturers of and dealers in photographic paper, etc. The subscribers (each with one share) are:—H. A. Nutland, 113, Redforth Avenue, New Malden, Surrey, company registrar; J. A. Ratray, 2, Cemnaes Cottages, Hemel Hempstead, solicitor's clerk. The first directors are to be appointed by the subscribers.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. D.—Some samples of persulphate do not work until a little acid is added, say, two or three drops of 10 per cent. sulphuric acid to each ounce or so of ammonium persulphate solution.

S. A.—Water-colours are largely used without any medium for colouring bromides, the prints being simply prepared by rubbing lightly with purified ox-gall. Perhaps you have in mind the wax medium for water-colours which is now used and is obtainable from Mr. V. Godbold, 93, St. Asaph Road, Brockley, S.E.

W. N.—We think the best book for your purpose is "Photography of To-Day," by Chapman Jones, which you can buy through our publishers, price 8s. You will find something there on the earliest genesis of the camera, which, of course, is several hundreds of years older than photography, and also enough on lenses for your purpose.

C. C. S.—1. We do not know any make of reflex camera in which plates are carried in a magazine. So far as we know, no camera of this kind has ever been put upon the market, and we hope it never will, for it would be abominably heavy in anything but the very smallest sizes. 2. We are sorry we cannot identify the "Flexit" camera, either as a reflex or other type.

H. W.—There is now no formality necessary or possible in order to establish copyright on a legal basis. If you have taken the photograph "on your own" you automatically become the owner of the copyright. If, on the other hand, you are paid for taking it, the copyright becomes the property of the person who paid you, or even the person who ordered you to take the photographs.

W. M. A.—You should certainly have received a fee for reproduction of each of the photographs, the minimum fee being 10s. 6d. It is not the custom of newspapers to return prints which have been reproduced. If we were you we should simply write a note pointing out that prints, the copyright of which is your property, have been reproduced in such-and-such an issue, but that apparently the payment to yourself of the fee for reproduction has been overlooked.

J. G.—Formulae for glazing solution is somewhat a matter of mixing and trying how it works. The basis of glazing solutions is ox-gall, which you can buy in a purified state from Messrs. Rheinlander and Sons, Rodney Road, New Malden, Surrey, or prepare for yourself according to the instructions given in the "B.J." of June 6, 1919, page 316, obtainable from our publishers, price 4½d. post free. Formaline is often mixed with the ox-gall, and so also is a certain proportion of alum, but in our experience ox-gall alone is as good a glazing solution as any.

W. S.—You do not tell us the height or other dimensions of the room, so we cannot advise you very well as to the artificial light, but it looks as though for your stickyback work a single 2,000 candle-power half-watt lamp or one of the Toplight arc lamps of the Westminster Engineering Company would be the best for your purpose. You had better write to the Westminster Engineering Company, Victoria Road, Willesden Junction, London, N.W., and to the General Electric Co., Limited, 67, Queen Victoria Street, London, E.C., as regards their half-watt lamps.

W. B. C.—You will not get half-second exposures with two blow-through lime jets, nor, we should say, with half a dozen. The candle-power of the average oxy-hydrogen limo is approximately 500, and you want about 3,000 candle-power at least for really quick exposures under the conditions you mention. The light is

about the least suitable for illumination of a figure for portraiture owing to its extremely concentrated form. So far as we know, there are no measurements, even rough, of the candle-power of magnesium ribbon, but it gives, we should say, about 800.

S. H.—Oil lamps are a very long way behind a decent incandescent gas burner for enlarging. You are certain to find that exposures are inconveniently prolonged, and you will have some difficulty in getting uniform illumination with the three-wick lamps supplied to ordinary magic lanterns. Our opinion is that if you figure it out you will find that the price of gas has very little effect on the actual cost to you of the enlargements, but if you must have another light, about the best is the "Luna" lamp made by Messrs. W. C. Hughes, 82, Mortimer Road, Kingsland, London, N.1. This burns methylated spirit and probably costs as much to run as incandescent gas.

N. H.—Without having tried it, we should think that a celluloid coating would not work for transfer paper, as it would not give sufficient adherence between the two films. Probably the cause of your veiling of the high-lights is due to colour in the gelatine. Do you use the finest emulsion gelatine? As regards the true-to-scale process, the blue-print is applied dry and removed dry from the gelatine mixture, which is then inked up and impressions taken by contact. There is no wetting at any stage of the process. But it is not a process for reproducing drawings in colour unless you are ready to go to the trouble of inking up different parts in different colours. You could do that, but it would be a laborious business.

P. E. W.—We think the action at Blackpool was taken entirely under a municipal by-law. In some districts the police certainly do require photographic touts who go from house to house to have a hawker's licence, but the police practice in this respect varies considerably in every district. We expect you will find that your local authority considers that it has rights in regard to permitting photography upon the beach, and is ready to dispose of them to individual photographers for an agreed sum. As regards the pierrots, it is pure rubbish to say you are infringing any rights in making such a photograph as you have or in making any use of it. Having taken your photograph, you are the sole owner of the copyright in it, and, short of it being libellous, there is no restriction which can be put upon its use by anybody.

E. W.—There is no better colour than white for the dark-room walls so long as your illumination is safe, and if the illumination is not safe then no colour of the walls will make it safe, although it may, perhaps, help matters a bit. You cannot do better than have the walls painted or papered white, but be particular in having a proper safelight for the dark-room lamp and not ordinary ruby glass. If we were you, we should avoid daylight illumination altogether, but that is, perhaps, a matter of opinion. In any case, see that you have a yellow fabric as well as a ruby window for daylight use, and that you fix the fabric so that you can renew it from time to time, as it is liable to fade in the light. A ruby glass window for use in daylight, unless specially tested for safety, is liable to give fog.

H. F. C.—For critical definition at a large aperture to the corners of a half-plate, we are afraid there is nothing for it but one of the $f/4.5$ anastigmats of at least 8 inches focal length, preferably 9 or 10 inches focus. If bulk of copying apparatus is not an objection you could no doubt get a second-hand portrait lens of about 12 or 14 inches focus which would answer the purpose as well, and probably be distinctly more rapid. At the same time, you may be able to buy second-hand at a price a good deal below an anastigmat. If we were you, we should see what a firm of second-hand dealers could do for you in the way of the portrait lenses before deciding on the anastigmat. We have no doubt that if you put your requirements to them they would allow you the opportunity of trying three or four lenses for your purpose.

L. W.—If you are taking portraits and are being paid for doing so, there is no reason why you should not be given the customary professional discounts by suppliers of photographic goods. The best thing would be for you to have a temporary trade letter heading printed, and take up the question with one or other of the leading houses, such as Messrs. Houghtons, Griffins, or Kodak. If you trade under your own name it is not necessary for you

to register your business, but under the present Retail Businesses Licensing Order you require to obtain a licence whether you are carrying on the business at a studio or simply doing it at people's houses or wherever it is convenient. It does not matter that the place where you are now working is private; the essential thing is that you are carrying on photography locally, and that is permitted only by licence, the office for which is 80, Westbourne Terrace, Paddington.

A. F.—We assume from your letter that electric light is not available, so that you can only adopt some system of gaslighting. This will be rather difficult in a width of 7 ft.; and, if possible, we should advise you to place the dark-room elsewhere. There are two systems in common use: one is the Howellite and the other the Kodak. We should think it might be better in your case to dispense with a stand and fix a series of Howellite burners on the wall. If you send to Messrs. Griffin, Kemble Street, Kingsway, they will send you particulars and prices of their lamp (the Howellite). You should also ask for prices of burners separately. In any case there will be a considerable amount of heat, but this will hardly be an objection for the next few months. Cameras such as you require can be obtained from Messrs. Billcliff, Richmond Street, Boundary Lane, Manchester; or Messrs. J. Fallowfield, 146, Charing Cross Road, London, W.C.2.

A. J.—1. You will require to obtain a licence, the office for which is Harewood Barracks, Woodhouse Lane, Leeds; but you must bear in mind that this Order was made for the benefit of men like yourself, who have been in one or other of the Services, and, therefore, you should experience no difficulty in getting a licence. 2. There is no disadvantage except the extra cost in having five lamps instead of three, and you will naturally be able to give shorter exposures. If you do not require all the lights at once you will be able to vary the effect by switching off one or two, as may be necessary. The arrangement you mention will answer very well. The front lights should be about 8 ft. from the floor, so as to give enough top light; the side ones may come lower—say, 6 ft. The front light should be about 8 ft. from the back-ground and the nearest side light, say, 4 ft. 6 in. or 5 ft. If you can make them all to raise and lower it will be better. Do not have bright reflectors; the enamelled iron ones sold by the General Electric Company are the best for the purpose. Failing these, have white distemper, or even card reflectors. We should not advise white walls; it is better to have white reflectors where you need them for the shadow side. White or very light walls may give a flat effect.

SUMMARY.

At the meeting of the Council of the Professional Photographers' Association it was announced that the present honorary secretary has been appointed to act as paid secretary of the Association for the year ending December 31, 1920. (P. 641.)

The City and Guilds of London Institute, in agreement with the Board of Education, have withdrawn Grade I. of the examinations in pure photography and photo-mechanical processes so far as England and Wales are concerned. We give the syllabus of study prescribed for the Grade II. examinations which will be held in May next. (P. 637.)

It is reported that the Essen firm of Krupp is taking up the manufacture of photographic apparatus. (P. 639.)

A method of engraving finished Bromoil prints so as to simulate the effect of copper-plate etching is among the regrettable war-time products of an ex-enemy country. (P. 630.)

A method, described as the only satisfactory one, of using the persulphate reducer was mentioned by a speaker in a Croydon Camera Club discussion. (P. 642.)

In a leading article we deal with the general question of the effective fixation and washing of negatives. It is pointed out that thorough fixation is a necessary preliminary to effective washing, and that the latter operation can be done in a short space of time and with comparatively little water by working upon a rational system. (P. 639.)

The important uses which are being made of photographs in industry and sales-organisation are the subject of an article by Mr. G. D. Crain, Jun., which we quote from "American Photography." (P. 635.)

In his article this week "Practitioners" deals with the selection of an outfit for the beginner in professional studio and outdoor photography, pointing out the items which are of the first importance, and the selection of them which it is most advisable to make. (P. 633.)

A review of the scientific, technical, and colour sections at the exhibition of the Royal Photographic Society will be found on page 631. One of the most noteworthy exhibits is that of microscopically fine indelible scales on glass prepared for optical purposes by Messrs. J. and E. Rheinberg according to a process worked out by them.

In many studio establishments more attention is needed in keeping the dressing-rooms in "nice" condition. (P. 630.)

The making of transparent sensitive emulsion and its use in processes of colour photography figure in "Patents of the Week" (P. 639.)

In the cold damp weather of the winter season, measures require to be taken to obviate unduly slow drying of negatives. (P. 629.)

EX CATHEDRA.

A Pioneer of the Road. The "B.J. Almanac" has long been a great traveller. The present generation of its publishers has unfortunately no means of ascertaining with any pretence to accuracy the stage in its career as an annual publication at which it began to find its way overseas in large numbers. But as years have gone by it has continued to penetrate more and more widely into all parts, even the most remote, of the civilised world, with the result that at the present day those of its 25,000 readers who are outside the United Kingdom outnumber those within it. Regular advertisers in the "Almanac" have come to appreciate the value of the volume in maintaining contact with these overseas customers as well as in establishing relations with many photographers whose first acquaintance with the resources of British photographic firms is made through the bulky yellow or green volume. It is this pioneer circulation which no doubt has been a large factor in maintaining and exalting the supremacy of the "Almanac" as an advertising medium for photographic goods through 59 years. Moreover, the links thus established between England and the many distant parts of the world by the distribution of the "Almanac" are something more than those created by the issue of an occasional circular or catalogue: universal experience is that each copy of the "Almanac" is kept and used for at least a year (often much longer), so that the link becomes really a channel of communication along which much business flows. It requires to be said in conclusion that the 1920 "Almanac" is now in an advanced state of preparation, and that instructions for the insertion of advertisements require to be received by our publishers without loss of time.

* * *

Negative Drying. As soon as damp cold weather sets in some workers find a difficulty in drying their negatives quickly and evenly, and sometimes unsightly marks are caused by attempting to dry off plates which are wanted in a hurry. If possible the rack should be carried into a warm room as soon as the surplus water has drained off, and allowed to remain there till the morning. A common mistake where many plates have to be handled is to place them too close together in the racks, so that the moisture cannot get away. If space is limited, it is a good plan to wipe the backs and to place the negatives in pairs with the films outside. By doing this, double the distance between the films can be obtained in the same length of rack. Another good plan is to pass the negatives through a weak formaline bath. This hardens the surface so that the film may be wiped with a soft cloth, after which the plates may be placed quite near to a fire or radiator without risk of melting. Where

a small electric fan is available it greatly facilitates drying even in a cold atmosphere. For "rush" or press work there is nothing to equal the old plan of using methylated spirit, but at present this is too expensive for ordinary use. A great economy of spirit is effected by dabbing off all the surface moisture before putting the plates in the spirit.

The Dressing-Room. In a large number, perhaps in the majority, of studios the dressing-room is not of the standard of the rest of the establishment, being a kind of "no man's land" which does not come under the care of anyone except the charwoman. Even if originally well appointed, the fittings, if not cared for as they would be in a private house, rapidly become dingy and produce a bad impression on clients who are used to living amid decent if not luxurious surroundings. The fittings and decorations of a dressing-room should be designed to show up dirt and not to conceal it, and to this end it is desirable that the walls and such part of the floor as is not covered with rugs or carpet should be finished in white enamel paint, which can always be restored to its pristine purity with a little soap and water. D'oyleys or any similar furnishings should be kept scrupulously clean, and a sufficient supply of combs and brushes provided to allow of clean ones being placed for the use of each sitter who needs them, although most "nice" people prefer to bring these articles with them. Photographers of all classes will do well to give an eye to this department more frequently than most do at present.

Enlarging Apparatus. If a suitable dark-room be available a very efficient and economical enlarging apparatus can be made by fitting a condenser into one of the walls at a convenient height and placing an incandescent gas or electric light upon a shelf or bench outside. An ordinary camera fitted with a negative carrier instead of the usual reversing back is fastened close to the condenser, and, except for the easel, the arrangement is complete. It is unnecessary to point out the advantage of having the illuminant outside the room, from a sanitary point of view, if gas or oil be used, while in any case there is no risk of light leakage as from a lantern body. If an electric arc be available, the condenser may be dispensed with and its place taken by two pieces of ground-glass placed about a foot apart. These will be found sufficient to diffuse the light if negatives of half-plate size or smaller are used. For larger sizes a pair of lamps placed one on each side of the opening, with a sheet of white card to serve as a reflector, will be needed. We have used this method for sizes up to 12 x 10 very successfully both for bromide paper and for making enlarged negatives and transparencies, as well as for ordinary lantern-slide work. It is easy to get sufficient distance even in a small dark-room by working right across the sink.

Engraved Bromoils. Apparently the restrictions on photography in the enemy countries during the war have been responsible for turning the energies of some photographers into fresh directions. One of these which should provide ample occupation for the long winter evenings is the suggestion of a method of hand-engraving the finished Bromoil print. The process is described at great length by a contributor to an Austrian journal. The Bromoil print having been finished and dried in the usual way is then worked upon with a sharp blade, something in the manner in which half-tone blocks are tooled by the photo-engraver—that is to say, the ink image is cut away in fine lines, so as to break up the image in some places with a white cross-hatching, in others by various engraving touches considered appropriate to the lines in the subject. A speci-

men of the result of this process, reproduced in photogravure, shows it to be a dreadful hybrid of full-tone photography and copper-plate etching. No doubt it will find a few exponents here among the people who cannot be satisfied with the photographic qualities of an oil or Bromoil print, but must make them into something else by various adventitious means. Perhaps the best feature of the process is that the cutting blade which is suitable for the engraving of the ink image is a most difficult thing to get. The Austrian writer describes his many unsuccessful attempts, and explains that in the end he had to have knives specially made for him by makers of surgical instruments.

FIXING AND WASHING NEGATIVES.

A CORRESPONDENT of the "Pharmaceutical Journal" recently asked for a hypo-eliminator for treatment of negatives after fixing. In reply, the following method was given: After washing the fixed negative under the tap for a minute, transfer it to a dish containing water with sufficient potassium permanganate to colour it pink. As soon as the colour disappears, repeat the process with fresh solution until the solution retains its colour. It was stated that with this treatment the negative would be ready for drying in three minutes. This is evidently an under-estimate of the time required in the case of a negative to be preserved, and, at any rate, if the hypo were decomposed the decomposition compound would remain in the film, and that might have some deleterious effect, physical or otherwise.

It is doubtful whether any method of eliminating hypo is as quick and efficient as the scientific application of plain water. Moreover, it is pretty certain that the presence of pure hypo in the film, in quantity insufficient to affect the gelatine physically by crystallisation, will be harmless. When a negative goes wrong, after having passed through the processes of fixing and washing, in consequence of something from the fixing bath remaining in the film, it is not often that hypo is the active material. It is usually the decomposition product of silver and hypo. The first essential towards securing permanency is to take steps to leave as little as possible of this silver compound in the film on leaving the fixing bath. To this end the fixing bath should be fairly strong and used in reasonable quantity. Also, it should not have been previously too much used. Having been properly fixed, the ideal way of washing is to arrange the plate, film downwards, just below the surface of the water contained in a vessel of some depth, say, 6 or 7 inches. The water must be quite still, and must not be agitated while the plate is in position. The hypo will dialyse out and will sink to the bottom under these conditions. At least 90 per cent., probably more, of the hypo will be removed in five minutes, and another five minutes will remove as much as can be removed if before drying the surface moisture be absorbed with a piece of fluffless blotting paper or of well worn linen or calico.

It is obvious that if the finished negative is to be used at once, and if also (its immediate purpose being fulfilled) its permanency is unimportant, there is no necessity for the same precautions that would have to be taken in the case of a negative of future value. The "while-you-wait" postcard photographer must necessarily work with extreme rapidity. His method is to employ a small plate which, after being developed, is fixed probably not further than to remove the visible silver bromide, etc., and after a perfunctory rinse is placed in the carrier of an enlarging lantern while still wet, and postcards made thus. Negatives made and used in this way are not

likely to stand. If they are required for future use they should be returned to the fixing bath as soon as possible, and left there rather longer than the usual time for fixation and then washed and dried. Nevertheless, it must not be thought that this deferred fixation is as good as full fixation in the first instance.

Although effective washing is important, complete fixation is of far greater importance. A small amount of pure hypo remaining in the film will not have any action, provided the negatives are stored where they will remain perfectly dry. Pure hypo, even in solution, does not act on the silver image except in the presence of oxygen or air. A plate fixed in a dipping bath may be left there many days without any apparent action, but a plate left in a flat dish covered with hypo solution to an eighth of an inch in depth will show signs of action after some days. The difference in the two cases arises from the more perfect aeration of the solution in the latter case. Hypo is a less dangerous enemy than it is generally supposed to be when it has no allies acting with it, but with silver it forms compounds of deadly activity. Such compounds are formed in the fixing bath. Fortunately, their power for evil may be restrained. The chemical action of the fixing bath—really a series of actions—is very complex. An endeavour will be made to describe such action without technical terms in order that all may understand. Assuming that the film of a plate consists of silver bromide and gelatine, it must be first understood that hypo solution does not dissolve silver bromide in the ordinary sense; that is, as water dissolves sugar or salt. The action is a chemical one, followed eventually by a solution in the ordinary sense. Probably the first action results in the formation of a silver compound in which the sodium of the hypo is replaced by silver. This silver compound is so unstable that, but for further action between it and a further supply of hypo from the bath, it would immediately decompose with the formation of silver sulphide. This decomposition resulting in silver sulphide is illustrated by what occurs when a piece of bromide paper is handled with fingers damp with hypo solution—a brown stain of silver sulphide. However, in the presence of more hypo this does not occur, but a combination takes place between this unstable silver compound and a further supply of hypo, resulting in a new compound containing both silver and sodium with sulphur and oxygen derived from the original hypo. This compound is nearly insoluble in water, but is soluble in

hypo solution. It is colourless like hypo itself in that its presence is not visible, and it is to allow of the diffusion of this compound in the bulk of the fixing bath that it is necessary to leave the negative in the fixing bath for some time after the silver bromide has disappeared. The time allowed for fixation should be at least as long again as that required for the white silver bromide to disappear. If sufficient time is not allowed, that is to say if the plate is removed from the bath too soon, the result will be that even after copious washing some of this unstable compound will remain to manifest itself in time as a brown stain.

It will be clear from the foregoing that the fixing bath, after the fixation of every plate, becomes weaker in hypo while the silver compound accumulates. Fixation, therefore, takes place more and more slowly, and eventually the bath will cease to fix at all; but long before this stage is reached it should be discarded. A rough-and-ready test of the state of the solution is furnished by the fact that silver hyposulphite is an extremely sweet substance, many times sweeter than sugar, whilst hypo has a salt taste. If a finger be dipped in the bath and applied to the tongue, and there is the slightest perceptible sweetness, it is time to discard the bath.

To return to washing. A solution of hypo is heavier than water; if, say, 2 oz. of a fairly strong solution of hypo be introduced at the bottom of a vessel of water, say, a tumbler or 10-oz. measure glass, by means of a long-necked funnel and the vessel be placed where there is no vibration, diffusion will not take place for many days. It is difficult to see the state of the solution, being colourless, but if the experiment be made with a strong solution of table salt coloured with a few grains of dye it will be visible. This experiment will show that the least effective way of washing a negative is to leave it face upwards in a dish of water without motion. Running water is very much more effective, but a still better way is to rock the dish continually, and to change the water every two or three minutes, the washing extending over twelve to fifteen minutes. The ordinary rack washers, where the water is flowed in at the top and removed from the bottom, are quite effective if sufficient time be allowed. Prolonged washing does not improve negatives in any circumstances, and in hot weather it is particularly undesirable. With any reasonable system, half an hour is quite sufficient to remove everything that is removable.

THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

SCIENTIFIC, TECHNICAL, AND COLOUR SECTIONS.

ALTHOUGH the technical sections at this year's exhibition are not large, they contain much interesting work. The great majority of this, however, consists of examples of the application of photography to nature study, radiography, meteorology, astronomy, etc. It may be said that the days are gone when an annual exhibition such as that of the R.P.S. can hope to contain many exhibits of fresh interest in the domain of pure photography. Of late years new photographic processes or designs of apparatus have been few and far between, and their rarity has its counterpart in the technical exhibits of this kind which are offered to the Society. Nevertheless, the present exhibition contains several. Without question the most notable of these is that of Julius and Ernest Rheinberg (No. 315), entered as "Grainless Photography and Filmless Photography." Apparently, the title of the exhibit

refers to two distinct processes, but as no details of the methods are divulged the supposition is no more than speculation. But, taken altogether, the exhibit, which fully deserves the medal awarded to it, relates to the invention of a process of making exceedingly fine indelible scales upon glass. Such scales, under the name of graticules, were products (highly necessary for many optical instruments) which before the war were obtainable only from ex-enemy sources, and apparently were made by secret methods. Messrs. Rheinberg, at an early stage in the war, took up the investigation of methods of making these scales, and within a relatively short time brought their manufacture to a very high state of perfection. They show examples of many forms of scales, the lines in which, under high magnification, show no trace of granularity of structure, nor is such to be detected.

in the vehicle, if any there be, which holds the design of the scale upon the glass. It is, in fact, stated in the catalogue that the finished product is innocent of any colloid film whatever, the lines being indelibly incorporated in the surface layer of the glass. There are no doubt good reasons for preserving secret the details of such an invention, but the fact of secrecy should not lead one to leave unexpressed the most sincere congratulations to the two investigators on their success in applying photography to a process possessing the highest value in the arts of both peace and war.

Perhaps the next most notable exhibit in the sphere of pure photography is the prints by the modification of the gum-bichromate process demonstrated some months ago to the Society by Mr. Herbert S. Starnes. These are Nos. 345 and 346, and show the results obtained by a sensitive coating consisting of gum senegal and pigment together with bichromate, alum, and hydrochloric acid. Mr. Starnes shows some coloured prints, which we assume to be simply examples of hand colouring, although perhaps the description of the process might leave it to be supposed that the colours are fixed in some way by a photographic process. Two prints by H. F. Farmer (Nos. 366 and 367) are by the modification of the Ozobrome process, which Mr. Farmer calls "Carbro." They serve to show in a modest way the excellent tonal quality obtainable by the process. Two exhibits which probably will interest teachers of photography more than anybody else are Nos. 288 and 289. The former shows side by side the effects of irradiation and of genuine halation in an emulsion film; the other is an actual photograph of the path of rays undergoing double total reflection in their passage through a glass bar.

An exhibit of much interest to spectroscopists is that of the spectra of the copper arc (Nos. 361 and 362) photographed on the new type of colour-sensitive Schumann plate worked out and manufactured by the exhibitors, Messrs. Adam Hilger, Ltd. Messrs. Hilger also show photographs (Nos. 363-365) illustrating the use of the Hilger interferometer for the testing of photographic lenses. The instrument, the use of which was set forth in last year's Traill Taylor lecture, is based on the principle of showing the errors in the wave surfaces delivered by a lens, a system which is of extreme delicacy in disclosing characteristic aberration.

Nature Study and Photo-Micrography.

These two classes of exhibit need to be grouped together, since the photo-micrographic work consists almost entirely of examples of animal or vegetable structure. Among the photographs of animal subjects taken on a small scale of magnification, the most notable are those (No. 200) of mosquitoes, by Hugh Main. They show the mosquitoes of malaria and yellow fever. A medal is awarded to the photograph of British mosses (No. 204), by A. W. Dennis. Other photographs of lichen and mosses are shown by the same worker. A considerable number of photo-micrographs are shown by J. H. Pledge, F.R.M.S., who receives a medal for his series (Nos. 242-244) of the gonidia of a lichen. These range in magnification from 40 to 3,500 diameters. Dr. G. H. Rodman is a large exhibitor of photo-micrographs showing sound organs of the Mygale spider and stages in the life-history of the cuckoo-spit insect. Another series of somewhat the same kind is that (Nos. 258-269) showing the anatomy of the frog, by J. G. Bradbury. Photo-micrographs by G. Ardaseer (Nos. 235-237) are of the seeds of plants, it being pointed out that the magnified photographs are of great service in determining if a sample of seed corresponds with the name under which it is sold and are a means of detecting its adulteration with other commoner and therefore cheaper seed.

X-Ray Photographs.

Radiography is represented by a large selection of exceedingly fine work by Dr. Robert Knox (Nos. 209-217), all of the

human subject, and including a radiograph of the hand of an Egyptian mummy of 1500 B.C. But perhaps the X-ray photographs of chief interest are those by Dr. Knox in collaboration with Major G. W. C. Kaye, representing the examination of aircraft materials for flaws and defects by X-rays. The series (No. 232) marks the disclosure of knots, worm-holes, false packing, defective workmanship, and wrong construction in manufactured parts of aircraft such as spars and struts. Similar in kind are the two X-ray photographs (Nos. 230 and 231) by Hector Pilon and Geoffrey Pearce, showing in one case casting defects in the carburetter of an internal-combustion engine, and in the other the four sections of the cylinder of an engine.

Although not coming within the province of X-ray work, we may most appropriately refer here to the photo-micrographs of electric welds (No. 270) shown by Dr. B. Parker Haigh. These show sections of electrically-welded metal employed in structural work in ships, and were taken in order to emphasise certain faults, particularly brittleness in parts. In the case of the low-power photographs the surface of the metal was etched with nitric acid, whilst for the metal photographed at a high-power etching with picric acid was employed.

Meteorology and Astronomy.

Phases of cirrus clouds moving at two different levels are the subject of two photographs shown by G. Aubourne Clarke (Nos. 272-275). Mr. Clarke, whose long-continued work in the scientific photography of clouds has figured in previous exhibitions, also shows a striking rendering of cumulo-nimbus or thunderstorm clouds, and a very striking one, though in monochrome, of a rainbow accompanying a passing shower. A set of photographs showing the sequence of lightning flashes during a severe thunderstorm (No. 278), is the only other print of meteorological interest. It is by H. Hargrave Cowan.

Astronomical photography is but slightly represented. The Rev. A. L. Cortie shows a series of photographs of the spectrum of Nova Aquilae in 1918 (No. 276). The total solar eclipse of June 8, 1918, is the subject of three photographs (Nos. 279-281) by Professor Campbell, of the Royal Astronomical Society; whilst the amateur in this field of work is represented by F. Sellers, who contributes a series of lunar photographs (No. 277) taken with a reflecting telescope, of equivalent focal length about 20 feet, from the top room of an ordinary dwelling-house at Muswell Hill.

Colour Prints and Transparencies.

Three-colour prints make a small showing in the exhibition and are chiefly by the Raydex process. Of the prints by this process, the best are by John Bean (Nos. 341-344 and No. 356). The last named is a charming piece of work in the colour photography of flowers. There are two examples (Nos. 347 and 348) of the process of making three-colour prints from negatives of the Joly type, produced by a single exposure under a colour screen of linear mosaic pattern, details of which the exhibitor, Mr. S. H. Williams, recently published in a communication to the Society. The two prints are presumably superimposed gum or oil impressions, but no particulars are given of their origin. From the pictorial standpoint, by far the most effective colour prints are those (Nos. 357-360) by the Rawlings oil process, shown by A. Motteau. These evidently are not intended to be accepted as examples of three-colour photography, but are frankly the result of local application of coloured pigment inks to the faint photographic image.

In the collection of colour transparencies, the honours may be said to be shared by Mrs. G. A. Barton, Louis J. Steele, Lucien Talamon, and W. E. Gray. The latter shows but one example of the Autochrome process, but it is a particularly fine one of the brilliant colouring of "The King's Indian Orderly Officers" (No. 156). Mrs. Barton has indulged her fondness for pre-Raphaelite effects in her Autochrome work,

which technically is of a very high order. "The Blackberry Girl" (No. 170) and "Old-Fashioned Flowers" (No. 171) are examples, although we like best the study from Christina Rossetti's "Goblin Market" (No 178). In "Olivia" (No. 184) she has a very successful rendering of the very light tones of a white dress. One medal is awarded to Lucien Talamon for a large and exceedingly fine Autochrome portrait (No. 169) and another to Louis J. Steele for "Autumn Study" (No. 192).

Photographs of South Pacific Islands.

The library on the ground floor is occupied by a series of nearly 150 photographs by Thomas J. McMahon of scenes in the island groups of the South Pacific. Mr. McMahon is an Australian who has travelled extensively in the islands, and has witnessed the growth of many of them in industrial importance. His photographs, for example, of Nauru and Ocean islands, famous for their rich deposits of natural phosphate, bring vividly before one's eyes the immense natural resources of these far-away groups which, far from answering to the popular conception of jungle-covered islands inhabited by cannibals, are now almost as civilised as Cheltenham or Golder's Green, with their steam and electric railways and bungalows for the native labourers, fitted with bathrooms and electric light. The visitor to the Pacific who expects to see places such as he has read about in Herman Melville is likely to be just as much

disillusioned as, for example, was the late Marcel Schwob, the friend and interpreter of R. L. Stevenson, on the visit which he paid to Samoa after Stevenson's death, attracted to the island by the latter's romantic pictures of it. But if romance has taken second place, industry continues to progress in these South Sea Islands, and Mr. McMahon's photographs usefully supplement the message of his series of lectures to the effect that we of the British race require to bestir ourselves in order to secure and maintain British industrial interests in the South Pacific.

Trade Exhibits.

In the hall of the Society's house are shown wall displays by a few photographic firms. Messrs. Kodak, Ltd., exhibit a number of enlargements on Kodak bromide paper from negatives on Eastman Portrait film taken by Mr. Will Cadby. Portraiture by several well-known professional and amateur photographers forms the exhibit of Messrs. Thomas Illingworth and Co., Ltd. The prints shown are on the Illingworth "Bromide de Luxe." The Autotype Company have a varied selection of carbon work, and Messrs. John J. Griffin and Sons, Ltd., show an attractive set of prints on their Noctona and bromide papers.

The exhibition continues open daily (Sundays excepted) from 11 a.m. to 9 p.m. until Saturday, November 29.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).

Photographing Children (June 6).

THE QUESTION OF OUTFIT.

I HAVE often been asked to give a detailed list or specification of articles necessary for commencing business as a photographer, and sometimes I have undertaken the task of selecting them, which is not quite such a simple matter as it might appear unless the question of cost can be entirely disregarded. In previous articles the subject has been touched upon principally in connection with cameras and lenses, but many other articles are required, so that the matter is worth returning to. It is unfortunately impossible to give even an approximate idea of prices, as in this direction everything is in the melting-pot, and we shall have to wait many months before we know what manufacturers intend to put upon the market, and what prices are likely to be. There is still a

great shortage of materials such as wood, glass, brass, and other metals, and the wages question is still far from being settled.

First and foremost, we have to decide what articles come into our scheme, and I think it advisable to deal only with such as are needed in the actual production of the work, and to leave out such items as reception-room furniture, carpets, and shop fittings. I have before me an old "list of a photographic outfit," which commences with a glass-house or room in the garret, furnished with a skylight and concluded with hammer and nails, pins, needles and thread, and fire-irons, such weird things as stuffed birds and beasts and skeletons also finding a place. For the benefit of the

curious, it may be stated that this list appears in the "Silver Sunbeam," published in New York in 1879.

Manifestly, no single specification will suit every class of business, and even in the same class due regard must be paid to the amount of cash available, many articles which are very desirable but not absolutely indispensable having to be omitted when the funds are limited. I will take as my model what may be termed a good medium-class suburban or country business, where all varieties of work, indoor or outdoor have to be done.

In the majority of cases it will be found advisable to adopt 12 x 10 as the maximum size to be dealt with by direct negatives. Cameras of this size are not much more expensive than those for 10 x 8 or even whole-plate, and at any time a single job may be offered which would cover the additional cost. Therefore, as the first item in the outfit, I place a 12 x 12 studio camera. This should have long bellows extension, and in addition to two 12 x 10 slides be fitted with a repeating back attachment for cabinets, with two or more slides, each carrying two half-plates side by side; suitable inner carriers will allow of these slides being used for post-card or quarter-plate negatives. A shutter, worked by pneumatic ball and tube or Antinous cable, should be fixed inside the camera; either the velvet flap or Packard Ideal patterns are good and not liable to damage. The circular bellows shutter answers well as long as it is in good order, but it will not stand rough handling. The studio camera stand should possess considerable range from high to low positions. I prefer the Hana and Semi-Centennial stands on this account, as it is easy with this type to bring the camera low enough to photograph children playing on the floor. A good large focussing cloth, or, better, a canopy arranged to serve both as lens shade and focussing cloth, is a necessary accessory. Unless very short-sighted, a focussing magnifier should also be provided, as it saves unnecessary eye strain and ensures quick and accurate focussing.

Lenses are accountable for a large portion of the cost of a studio outfit, and great discretion is needed in choosing them, as the length of the glass-room has to be taken into consideration. Of the older type of portrait lenses focal lengths of about eleven and nineteen inches will be found most generally useful. Ross's No. 3 cabinet lens and the same maker's 13 x 11 Universal Symmetrical ($f/5.6$) or Dallmeyer's 3 B and 5 D Patent Portrait lenses are popular favourites. Just now these may often be obtained secondhand at about pre-war list prices. A lens of shorter focus for small work should be added if possible. Ross's No. 1 Cabinet or Dallmeyer's 2 B Patent, both about $8\frac{1}{4}$ inches focal length, with an aperture of $f/3$, would be a good choice. If the additional expense is not objected to anastigmats of approximately similar focal length and aperture to the portrait lenses already mentioned may be selected. There is now a considerable variety of these upon the market, and they require an expert to detect any difference in quality, so that I need not particularise them by name. No attention should be paid to the covering power claimed by the makers, as this would probably lead to lenses of too short a focal length being chosen.

A greater focal length than 19 inches is desirable if many large heads have to be taken, or if a larger plate than 12 x 10 be used, and for this purpose a portrait lens of 24 to 30 inches focus should suffice, as anastigmats of this size are not only very costly, but unnecessarily good in quality, fine marginal definition not being required.

One or more reflectors will be needed, as well as a couple of circular head screens, one of the latter being covered with thin white material, and the other with black gauze. Kodak, Ltd., and Marion and Co. list good patterns of these articles.

Backgrounds do not call for the outlay which was needed when elaborate scenery was used and a dozen or so at £3 to £4 each could be found in many studios. One each, white, black, and

grey, will answer most purposes, and it is desirable to have these with a continuous foreground. A couple of smaller grounds graduated or with a suggestion of foliage will be found useful for heads and three-quarter lengths. The studio walls should always be decorated so that they can be used as backgrounds for groups or interior effects.

I strongly advise the provision of a head-rest. This may seem old-fashioned, but some of our younger workers are beginning to discover its value for standing figures.

Furniture may be acquired as needed, or rather as opportunities arise, as many suitable chairs, settees, and the like may be picked up at furniture shops. A beginner will do well to pay a visit to the showrooms of Kodak or Marion, where excellent reproductions of furniture suitable for portrait work may be seen. A good baby-holder, either in the form of a chair or to be placed upon a table, will save many anxious moments in the course of a year.

The dark-room fittings should be as complete as funds will allow, as makeshifts cost time, and time is valuable, even in a one-man business. Enamelled iron dishes are most economical and easily handled, and these can now be obtained in all sizes. Fixing should be done as far as possible in tanks, and good washing tanks for negatives and prints are a necessity. An enlarging lantern may well be fitted in the dark-room, although this may not be needed at first. If there is no great volume of work it probably pays better to give enlargements to a trade house.

A good set of measures, from 1 drachm to 20 ounces, and two sets of scales and weights, a small one with glass pans and a larger one for hypo, sulphite, and other heavy chemicals. The workroom must have a very firm table for trimming upon, and if dry-mounting is done a Merrett's trimmer is almost indispensable. The dry-mounting press should be as solid as possible, as less labour is required than with a small machine, which calls for dead pressure with little leverage to help.

It is needless to particularise such small items as plate racks, clips, blotting books, bottles, and retouching and spotting materials, although they have all to be bought and paid for, but I must say a word about the retouching desk. Do not economise upon this as far as size is concerned, remembering always that the desk is for the convenience of the worker and not merely a holder for the negative; the roughest deal frame two feet square is better than the elaborate mahogany toy, which measures 12 ins. or less over all.

Now for a few words on outdoor outfits. Here, again, I vote for 12 x 10 as the standard size, and, although smaller cameras are sometimes convenient, it is as well to be ready for large work from the beginning. Most group work, athletic, wedding, or otherwise, is done on 12 x 10 plates, and it is throwing away money to offer smaller work. I prefer the parallel-bellows pattern, but it is rather heavy for a single-handed worker, therefore a good, strong conical bellows camera will be most generally acceptable. Three slides should be provided, and I have found that an attachment for carrying half-plate slides in addition has been profitable.

At least two lenses are needed, and if possible these should be anastigmats, one of, say, 16 inches focal length and the other for wide-angle work about 7 inches. It is advisable to use lenses of which the separate components can be used at full aperture, after the style of the Holostigmats or Ross Combinable; lenses of this type may have extra components added to the set from time to time. If anastigmats are found to be too costly, the large lens at all events may be a rapid rectilinear by a good maker; such a lens should give satisfactory definition over the plate at an aperture of $f/16$, and this aperture is generally as large as the depth of an ordinary group will allow. The tripod should not be too light, and

should have a large head. Many cameras have had the baseboard split through being insufficiently supported by a small round tripod top. The outdoor focussing cloth should

always be of rubber cloth, as this not only excludes light perfectly, but is a good protection in case of a sudden shower.
PRACTICUS.

NEW BUSINESS USES FOR COMMERCIAL PHOTOGRAPHS.

[As is perhaps generally recognised the unconventional in thought and action makes headway more rapidly in the United States than in the older European countries. In photography the phenomenon has undoubtedly been a predominant factor in the development of pictorial work during the past twenty years; it can be traced also, although in smaller measure, in studio portraiture, and it seems now to be observable in the newer field of commercial photography. Support of this view is provided by two recent articles, which we print as one, by Mr. G. D. Crain, junr., in "American Photography," dealing with the industrial and commercial use which is being made of photographs. While it must be admitted that the demand for photographs to be used for such purposes as these must come from the customer, the opportunities for suggesting such uses are often open to the photographer, and it is therefore well that those of our readers who have an interest in the making of commercial photographs should keep themselves informed of the lines along which photography is being applied in other countries in industry and commerce.—EDS. "B. J."]

I.

THE well-known fact that demonstration beats argument in a dozen ways is responsible for the fact that photographs are used in business whenever a really concrete and definite image is desired. It is very well to use words to supplement the idea; but the picture, which, as has been well said, speaks a universal language, is a correct foundation to build on.

Manufacturers are studying accident prevention more carefully at present than they have ever done before. There are several reasons for this. The desire that every humane employer has to keep his workers safe from injuries has been responsible for much careful and painstaking research along this line; while the adoption of workmen's compensation laws in twenty-four States, and the certainty that many more will put such statutes into effect in the near future, has had not a little to do with the effort to remove the accident hazard as far as possible.

The rates for liability insurance necessarily go up as soon as compensation laws are made effective, the reason being that while damages are frequently escaped by the manufacturer in States where the common law defences of fellow service, voluntary assumption of risk, and contributory negligence may be pleaded, it is known in advance that payment must be made for accidents if a compensation statute has been put on the books. The knowledge of the definite, inevitable cost of accidents has put the prevention of them on what might be called a commercial basis, and has made it a matter of financial importance to every manufacturer to keep down the number of injuries inflicted by his machinery to the irreducible minimum.

The question which is most often presented in this connection is how best to show the operative of a machine its dangers and how best to impress upon him the need for care. A graphic suggestion is required and a constant reminder is also necessary. What fits the needs of the situation better than photographs? In fact, no other method can be suggested that will "fill the bill" so completely, so effectively, and so economically.

The writer recently visited a large cotton mill in a southern city, and was interested to note that on the walls of the plant, in all departments, are framed placards carrying photographs of the right and wrong way to perform certain operations. Under each picture was an explanation of the merits or defects of the method illustrated, the result being that the most ignorant or careless employé could not fail to appreciate the points made by means of the pictures.

A general hazard which was exposed was that involved in handling belts. The shifting of belts and the handling of transmission equipment generally form one of the greatest departments of accident production; and as this is a general hazard which exists in every manufacturing plant, it may be worth while to note the explanation which went with the pictures.

"Keep on the right side of pulley when putting on belts," said the placard. "In putting on a belt properly, the operator stands on the 'down' side of pulley, thus running, whose rim is moving toward him from the top. The chance of accident is practically removed by the exercise of ordinary care when putting on a belt from this side.

"In putting on a belt in the wrong way, the operator is standing

on the 'up' side of pulley, and should he slip and his sleeve or some other part of his clothing be caught by a set screw, key, or some other projecting part of the pulley, or under the belt, he might get carried over shaft, or possibly wound around it.

"Always keep sleeves rolled up, as shown in both pictures."

The cotton manufacturer also had pictures dealing with special hazards which are confined to plants of that kind, such as the proper and improper way of operating a picker, the correct and incorrect way of shifting a card belt, the right and wrong way to start a lap machine, etc. With each pair of pictures went the accompanying explanations, which indicated in impressive style just wherein the dangers of the wrong side of operation lay.

An incidental feature of the photographs, which was of great importance, however, was the mode of dress and the manner of arranging the hair. The latter is a particularly important feature in plants where women are employed. The photographs taught the operatives that their sleeves should be kept rolled up, and that their hair should be arranged neatly on the top of the head, and not allowed to hang in a braid. The regulations regarding dress were, of course, rigidly enforced, and this feature of the hazard can be more easily eliminated through ordinary supervision than the dangers connected with machine operation, where a momentary slip by the operative may cause serious injury.

The insurance company which handled the risk of the cotton mill referred to complimented it highly on the use of photographs for the purpose of preventing accidents, and has recommended the same plan to other manufacturers. The officers of the company are likewise convinced that the plan, which has been in use for about two years, is an excellent one, the following comment being made on the system:—

"While we put up these photographs without knowing just what the results would be, we have found that they have reduced accidents measurably. We have had no accidents whatever on the cards or pickers, which formerly were responsible for frequent and rather serious injuries being inflicted. We feel that the graphic way in which the dangers have been called to the attention of our employés, so that the most unintelligent can see the proper way to operate the machines, should be given credit for a large part of the improvement in conditions. We find that our people as a whole are interested in the photographs, and while it is true that familiarity breeds contempt, and that the old hand may disregard the injunctions given through the announcements, the general results are sufficiently good to warrant keeping them in place."

The adoption of compensation laws, referred to above, is ultimately going to result in each manufacturing plant being rated for liability insurance exactly as it is rated for fire insurance—on the basis of the hazards which exist there, and not in the class as a whole. In other words, each risk is going to be analysed, and the plant which has adopted the most and best methods of reducing the hazard and preventing accidents will get the lowest rate.

The use of photographs in this connection, in view of the actual results which have been experienced, and in consideration of the strong commendation expressed by the liability insurance company

which handles the risk of the manufacturer whose plan has been described, would undoubtedly have to be considered as a factor in eliminating the hazard, and consequently a credit would have to be given in the rate.

The importance of this factor lies in the use which could be made of it as a selling argument. A commercial photographer in a manufacturing town, after familiarising himself with the situation in his community, could go out among the manufacturers and suggest that photographs be taken for the purpose of accident prevention, explaining that the plan has been tried by others, and has proved successful, and mentioning also the credit in the insurance rate which may be expected by resorting to this device. While the analytical rating system may not be in effect generally at present, it is being worked out, and ultimately will be almost universally used.

Machinery manufacturing concerns are among those who would find the photographic system a valuable one, as injuries inflicted through the improper operation of machine tools are usually rather serious. Woodworking plants also contain a number of hazards, and while many of them can be eliminated by the installation of guards, the method of operating the equipment is nevertheless a most important factor, and the use of photographs would have a vital bearing on the situation.

The live commercial photographer in a city of any considerable size could get enough business in this way to keep him going for months; and, in view of the importance of the use to which the pictures would be put, as well as the need of more than ordinary skill in making the exposures, a much higher rate than charged for ordinary work would be in order.

II.

The use of photographs in lieu of samples, or for the purpose of supplementing samples, is now being so rapidly extended that there is really no telling where it will stop. New lines are continually being added to those whose salesmen are equipped more fully with a judicious selection of photographs than their predecessors ever were with a battery of heavy trunks loaded with samples; and where is the photographer who is not prepared, once alive to the situation, rather to help the movement along by his own active work than to retard its development by lack of interest and initiative?

At first glance the textile industries, including all of the wide variety of manufactures which involve the use of woven fabrics, from suspenders to sweaters and from neckties to underwear, would seem to be a rather unpromising field for the work of the photographer who knows how to make samples show up in pictures at least as well as the real thing, if not a little better. It would seem to the man who has not tried it that if any goods can be handled easily and well by sample, woven fabrics of various sorts and the garments made from them would be the goods. But the entering wedge has been driven, and the idea has taken hold on the textile trade, all because the thing has been tried and has been found immensely practical from every possible standpoint. It is true that so far as fabrics themselves are concerned it is easy enough to carry samples, because samples can be made as small as desired; but the difficulty and the woes of the travelling salesman lie in the fact that the enterprising manufacturer gets out a wide variety of models; and that is the answer.

Naturally, it is necessary, in order to show the line of goods to prospective customers, to have at least one of each model made; and as the number of different models multiplies, so multiplies the weight of the salesman's trunks, and the labour of going through them, and the time taken from the merchant in looking over the line. It seemed unavoidable, however, until some manufacturer—one in a western city—discovered the use of photography, or a photographer discovered him, it doesn't particularly matter which. At any rate, this was about the process of reasoning, and it might have been used by either the manufacturer or the photographer: "All that the merchant wishes to know about the fabrics which we use in making up our goods is their quality—whether they are of wool or cotton, how finished, and so forth. When he has satisfied himself on that point he is through as far as fabrics are concerned. Of course, he wishes to see how our various models look, which is the reason why we have been hampering our salesmen with ten or a dozen trunks; but is there any reason on earth why the models cannot be shown as well, if not better, by photographs? None, apparently; it is certainly worth trying, at any rate."

And it was tried, and, as a matter of actual fact, it developed that as far as showing the models was concerned the photographs had a distinct advantage over the old-fashioned method of carrying the mass, or mess, of samples in this, that in nearly all cases photographs could be taken not only of the garment itself but of a living model wearing the garment; whereas there is hardly anything less attractive than a limp and crushed garment dragged from a sample case and spread over a counter or a chair. And while a model on the spot would doubtless be better, there are insuperable practical difficulties in the way of carrying or procuring afresh in each town a complete staff of suitable models for a good-sized line.

A happy combination of the old and the new system was, therefore, decided upon by the aforementioned manufacturer, who handled a wide variety of lines. By the liberal use of the services of the fortunate commercial photographer who handled his business he covered his entire line, as far as models went, completely, with a separate photograph of each standing alone and upon a model. Where colours were important he had the photographs delicately hand-coloured, making them as lifelike as the thing itself.

Looking over this set of photographs, which were bound into neat books, each line having its own volume, he was enthusiastically satisfied that as far as models were concerned he had the situation covered. Turning his attention then to the necessity of showing fabrics and finishes, he met this need by the use of swatches of the fabrics used in each line—books of samples, as they might be called—supplemented by a few samples, a mere fraction of the number once carried. And the whole outfit, which was really infinitely more satisfactory from every business consideration than the old one, was much smaller and very much easier to handle.

This manufacturer, as stated, handled a number of different lines, any one of which might be turned out exclusively by a single factory. The method of handling them in connection with the photographs referred to might, therefore, be interesting. It was as follows:—

Suspenders.—About 150 samples, weighing 60 lbs. or more, were formerly carried by each man. Now a book of leaves on which a short section of the web and the ends and mountings are shown enables the display of the line to much better advantage, both as to effect and to time.

Blouses.—These formerly required a separate trunk; to-day, by the use of photographs and a half dozen actual garments, a 24-lb. package takes care of the line much more satisfactorily.

Underwear.—This line also required an entire trunk to itself. Photographs of living models, with a few samples, now give a much better idea of the line than formerly.

Sweaters, neckwear, dress shirts, wash goods, house dresses, children's dresses, and boys' wash suits are among the other lines covered in this way; and while some of them do not lend themselves as fully to the use of photographs as others, all have been handled with vastly less labour, both by salesmen and by retailers looking over them, than under the old way. And the efficiency of the photograph-plus-sample method of showing this particular class of goods is indicated by the fact that the manufacturer in question has noted a marked increase in his business since installing the new system for his travelling force, and naturally he is delighted.

The saving in wear and tear on the samples themselves is a very considerable item to the jobber who handles a number of different lines. The photographs are relatively inexpensive, whereas the samples in many cases cost a good deal, and as they have to be sold after use on the road at reduced rates the actual economy in money saved is easy to understand.

Another item worth considering, too, is that by cutting down the number of trunks and the weight of those carried the rather heavy expense of excess baggage is considerably reduced. The concern which adopted the use of photographs managed to reduce the number of trunks handled by its force by not less than 300, making a total of 7,200 lbs. of excess baggage entirely eliminated.

"The conservation of the salesmen's time is one of the greatest benefits," declared the jobber. "It is no small task to pack and unpack a dozen or more trunks once or twice a day. Frequently our salesmen each carried 1,700 lbs. of samples in the general line, and to handle these required much time and no little strength. To inspect them, moreover, a merchant had to visit the sample room in the evening, after a hard day in the store, and the result

was that he bought hurriedly. He wanted to get the disagreeable job finished as soon as possible, and did so. The salesman was tired, too; and it is only natural to lose enthusiasm as one loses energy.

"With our new system the men are carrying only about half the number of trunks formerly taken out, and selling more goods from the photographs than they ever did from samples. They are covering more territory, and average at least one town more a week; and, best of all, they are not tired out with handling a ton or so of samples daily, and are thus able to do their work much better."

In fact, the use of photographs in showing almost all lines of fabrics on the road has fully justified itself. The answer is obvious to the photographer with the desire and the ability to handle this kind of business. To paraphrase the famous advertising slogan used by a famous manufacturer of photographic equipment, not to mention that of an almost equally well-known soap-maker, "Is there a dry goods jobber in your town?" If there is he ought to be your "meat."
G. D. CRAIN, JUN.

THE COMPARISON OF THE DENSITY OF NEGATIVES.

The following method of comparing the density of negatives is devised to obviate the necessity of trial exposures in enlarging or contact printing by artificial light, and also to remove the element of conjecture as to the number of "tints" required in carbon work. Taking a negative of medium density as a standard, the relative density of any other negative can be obtained in a few seconds and recorded for reference.

The principle utilised is that of the Bunsen grease-spot photometer, familiar to physicists, and the apparatus is consequently simple and inexpensive. It consists, in fact, of two candles supported on square pieces of wood, a paper screen, and a graduated straight-edge, as illustrated in the diagram. The screen is constructed by cutting in a piece of stout card an opening slightly smaller than the negatives to be compared. A piece of paper, previously dampened, is mounted across the opening by means of a margin of glue applied to the card. When this is left to dry the paper will be found to be drum-taut. A rebated ledge, composed of two superimposed strips of card, is next affixed to the card on the paper side, so that the negative may be supported with the film side flush against the paper screen. With the base of the plate so held, any form of clip will suffice to hold the top in position.

The following mode of procedure was adopted to compare a number of negatives (1-plate). The screen (C) was set up vertically, with the candles (A and B) on either side, so that the points of light and the centre of the negative were in a straight line. The candle (B), on the negative side of the screen, was maintained at a constant distance of 10 ins. from the screen, while the candle (A) was free to move along the graduated straight-edge.

The negative selected to act as the standard was then inserted with its film side against the paper, and other lighting in the room was extinguished. Observing the paper side of the screen, and

shielding the eyes from the glare of the candle (A) by means of a card, this candle was moved from a distance towards (C). The shadow of the negative cast by the candle (B) on the screen became fainter and fainter until it finally disappeared. At this point the distance between (A) and (C) was measured along the graduated scale.

Negatives to be compared were then tested similarly, and a value for AC ascribed to each.

The standard negative was then printed on bromide paper to give a satisfactory print, the printing being carried out at a distance of

2 ft. from a batwing burner. The necessary exposure for the other negatives was then obtained by employing the following calculation:—

Let "S" equal distance AC for standard negative,
"D" equal distance AC for compared negative,
"t" equal exposure for standard negative, and
"x" equal exposure it is required to find.

$$\text{Then } \frac{x}{t} = \frac{D^2}{S^2}$$

$$\text{i.e., } x = \frac{t}{S^2} \times D^2$$

Now the value of $\frac{t}{S^2}$, having once been found, is a constant for all cases, and becomes a factor by which we multiply the value of AC² for any given negative in order to arrive at the comparative exposure for that negative.

The standard negative taken required 15 secs. The value of AC for the standard negative was 8.4 ins. The factor is therefore as follows:—

$$\frac{t}{S^2} = \frac{15}{70.56} = .21$$

Some widely varying examples were taken, and the results tabulated thus:—

Negative.	AC	AC ²	AC ² × .21
Standard	8.4	70.56	15.0 secs.
1	7.4	54.76	11.5 secs.
2	22.4	501.76	105.4 secs.
3	7.0	49.00	10.3 secs.
4	6.0	36.00	7.6 secs.
5	18.5	342.25	72.0 secs.

In the case of excessively contrasty negatives it is best to content oneself with the disappearance of the portions of the negative in which it is desired to obtain most detail; and it is realised that this method takes little account of stained gelatine. At the same time it is claimed that it possesses advantages over pure guesswork, is simple in operation, and quicker than the method of trial exposure and development.

HENRY W. G. BIDGOOD

THE CITY AND GUILDS EXAMINATIONS IN PHOTOGRAPHY.

The programme of the examinations to be held next year by the City and Guilds of London Institute deals with photography amongst other technological subjects. As in recent years, the acting examiners for 1919-20 are Mr. H. Chapman Jones and Mr. Charles W. Gamble. An important change, however, has been made in the examinations held in England and Wales: presumably it does not apply to Scotland and Ireland. This change, so far as it relates to England and Wales, appears to have been made somewhat hurriedly, since the announcement of it appears in the "Programme" as a special inset, printed in red ink, whilst reference to it is not discoverable elsewhere in the manual. The change consists in the abandonment of Grade I. of the examination, both in pure photography and photo-mechanical processes. It appears that this decision has been come to in agreement with the Board of Education, and is the result of the opinion of the latter Board that examinations held by outside bodies or institutions have the tendency to interfere with the satisfactory working of the system of instruction in grouped courses of allied subjects. The City and Guilds of London Institute, which for many years past has done most valuable work in encouraging the systematic study of technological subjects by its series of examinations, has therefore agreed to discontinue, in England and Wales, examinations in Grade I. of the various subjects, and in Grades I. and II. in the case of subjects where the examination is held in three grades.

While we have never been pledged to the view that the examination as a test of efficiency or an encouragement of study is the best for the purpose, yet during the many decades in this country when technological training was shamefully neglected by the Government, the examinations held by the City and Guilds of London Institute

provided an incentive to study, and benefited the progress of numerous arts and crafts to a degree which must always be borne in remembrance to the credit of the Institute. At present we do not know what form of examination or test is to be substituted for Grade I. City and Guilds examinations which are now being withdrawn, but it still seems of service to draw to the notice of the many more serious students who are to be found in the ranks both of photographic assistants and amateur photographers, the programme of study which is, or rather has been, prescribed by the City and Guilds of London Institute for more elementary students. It is even necessary to do this, for the reason that in the advanced or Grade II. examination the student is expected to have a wider and more understanding knowledge of the matters in the syllabus of Grade I. We may, therefore, quote from the "Programme" of the Institute the particulars of both grades—of Section A, pure photography; and Section B, photo-mechanical processes.

PURE PHOTOGRAPHY.—GRADE I., SECTION A.

The examination will include questions on such subjects as the following:—

1. The elements of photographic optics. The photographic camera and its adjuncts, lenses, diaphragms, shutters, shades, etc.
2. The practice and theory of the gelatine dry-plate process, including the use of colour sensitised plates, lantern-slide making, copying and enlarging, but exclusive of emulsion making; the composition of and defects in gelatine dry plates; the defects of gelatine negatives and transparencies, their causes and remedies.
3. Various methods of developing, fixing, intensifying, and reducing negatives, with a general knowledge of the chemicals employed.
4. Silver printing by print-out processes, including vignetting and printing in clouds, toning, and fixing; printing on gelatino-bromide and "gas-light" paper; platinotype printing.
5. Spotting and mounting prints
6. The studio, dark-room, and printing department, and their requirements. Lighting of the object to be photographed.

PHOTO-MECHANICAL PROCESSES.—GRADE I., SECTION B.

The examination will include questions founded on the following subjects:—

The apparatus used for negative making both in the studio and in the dark-room. The elementary principles of negative making—the formation of images by means of lenses, the action of light upon sensitive surfaces, development, and fixation. Practical details of importance in the manipulation of the wet collodion, collodion emulsion, and gelatino-bromide processes.

A simple knowledge of the properties of proteid substances as used in photo-mechanical photography—albumen, gelatine, gelatose (fish glue and the like), and their behaviour towards reagents. The chromates and bichromates, and the preparation of sensitive media.

The principles and practice (in so far as relates to essentials) of the following:—

The production of a relief block in line and half-tone, and the direct and transfer processes of photo-lithography.

PURE PHOTOGRAPHY.—GRADE II., SECTION A.

Written Examination.—Candidates will be expected to answer more difficult questions in the subjects of Grade I., and, in addition, a knowledge will be required of:—

1. The history of photography, with a general knowledge of obsolete processes (including the collodion processes).
2. The theories of the photographic image, of development, fixing, intensification, and reduction.
3. The theory of light as applied to photography, including a general knowledge of spectrum and orthochromatic photography.
4. The principles of photographic optics.
5. The theory and practical use of sensitometers for testing the speed and gradation of plates; and also their uses in printing processes.
6. The principles and practice of the preparation and use of gelatine emulsions.
7. The use of artificial light. Telephotography. Photomicrography.
8. Carbon printing; methods of printing with bichromates and with iron salts; enamels.

9. The theory and practice of colour-photography.

10. The application of photography to scientific and technical purposes.

Practical Examination.—Candidates will be required to show proficiency in conducting any of the following practical operations:—

1. Finding the focal length and aperture of a lens. Examining a lens as to its aberrations by simple methods, and its suitability for various photographic purposes.
2. Testing the sensitiveness and gradation of photographic materials.
3. Copying a drawing, engraving, transparency, etc.
4. Making enlargements from a quarter-plate negative.
5. Reducing and intensifying photographic images.
6. Printing, toning, developing, fixing, and mounting prints by any of the current processes (including silver, platinum, and carbon).
7. Making a lantern-slide by contact or in the camera.
8. Orthochromatic photography.
9. Colour photography by screen-plate processes.
10. Testing coloured materials as to their fitness in connection with the illumination of the dark-room. Testing colour screens for other purposes.

The care, cleanliness, and neatness with which candidates execute their work will be taken into account in the award of marks.

Specimen Work.—Candidates will also be required to forward, so as to reach the offices of the Department not later than April 26, 1920, not fewer than three or more than six negatives, not less than quarter-plate size nor more than whole-plate, together with mounted prints made from each of them by any ordinary photographic printing process or processes that the candidate may select. The negatives and prints must be accompanied by a statutory declaration made by the candidate to the effect that the selection of the subjects and the whole of the work (except the manufacture of the plates, sensitive paper, and mounts) involved in the production of the negatives and prints has been done by the candidate without assistance from any other person and within the twelve months preceding the date of the examination. Forms for the declaration may be had on application.

PHOTO-MECHANICAL PROCESSES.—GRADE II., SECTION B.

Written Examination.—Candidates will be expected to answer questions of a more advanced nature in the subjects of Grade I., in addition to the following:—

The principles underlying the photographic rendering of colour. The correct translation of colour into monochrome. The different methods which are employed in photo-mechanical processes for the rendering of gradations of light and shade. The principles and practice (in so far as relates to essentials) of the following processes:—

1. The production of three-colour blocks by the type-high process.
2. Photogravure.
3. Collotype.

Candidates are reminded that in the written papers more value will be attached to answers which show a knowledge of the essential principles involved than to lengthy details of a merely manipulative nature. They are urged, therefore, to pay special attention to the theoretical parts of the subject. They must also understand that the practical test is a very important part of the examination.

Practical Examination.—The candidate will be required to show proficiency in practical operations in one of the above processes, numbered (1), (2), (3), including the preparation of negatives suitable for the class of work chosen; or, in lieu thereof, he may select (4) negative making alone, in which case he must be prepared to take tests in any two of the following groups:—(a) continuous tone negatives from pictures in colour, (b) continuous tone negatives from drawings in monochrome and photographs, (c) continuous tone negatives from objects in relief, (d) broken tone (screen) negatives from monochrome originals such as wash drawings or photographs, (e) line negatives from originals in line, such as pen and ink drawings, wood engravings, plans or tracings. Notice must be given to the local secretary as to the test which the candidate will take at the time of his application for examination.

SPEAKING FILMS.—According to a Reuter report from Stockholm, a Swedish engineer named Berglund claims to have solved the problem of the so-called "speaking film," having obtained by a method of photography the absolute synchronisation of movement and sound. The invention has already been demonstrated to a number of Press representatives, who were most enthusiastic in their comments.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications October 13 to 18:—

CAMERAS.—No. 24,973. Film photographic cameras. A. W. Dodds.
FILM ADAPTER.—No. 25,384. Adapter for adapting roll-films for cameras. J. P. Dukinfield.

COLOUR PHOTOGRAPHY.—No. 25,208. Colour photography. Natural Colour Pictures Co.

PROJECTION SCREENS.—No. 25,490. Manufacture of cinematograph, etc., screens. W. L. Bemrose and J. W. Verity.

CINEMATOGRAPHY.—No. 25,571. Film trap or gate of cinematographs. J. Ballantine.

CINEMATOGRAPHY.—No. 25,150. Renovating cinematograph films. W. F. M. Edwards.

CINEMATOGRAPHY.—No. 25,016. Apparatus for producing halo, scintillating, and prismatic colour effects in cinematography. T. F. Gaynor.

CINEMATOGRAPHY.—No. 25,080. Method of attaching sprockets, gears and wheels of cinematograph projectors. H. E. Hartley.

COLOUR CINEMATOGRAPHY.—No. 24,982. Apparatus for production of coloured cinematograph films. S. de Prokudine-Gorsky.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRANSPARENT SENSITIVE EMULSION.—No. 132,846 (Sept. 18, 1918). The invention relates chiefly to an improved manufacture of photographic material which is transparent as well as sensitive. This is attained by augmenting the quantity of gelatine to an exceedingly high degree and diminishing the quantity of silver halide (such as silver bromide) in an ordinary photographic plate in which the compound is the only light-sensitive substance.

As an experiment in a laboratory the following method can be used. A silver bromide plate of 9 by 12 cm. is placed in water so that the gelatine is soaked, and the emulsion is scraped off and dissolved in a water bath. To this small quantity of emulsion is added 40 cc. of a 6 per cent. solution of gelatine at, for instance, 40–50° C., and the mixture is well shaken. 20 to 30 plates of 9 by 12 cm. can be thinly coated by the emulsion produced from this one plate, which plates are sensitive and perfectly transparent even if several such plates are superposed.

When such a plate is exposed in a camera, a negative which is exceedingly thin and quite unfit for ordinary printing is obtained after development and fixing; but from such a negative a picture can be produced by copying. For instance, these plates can be intensified by known methods thereby obtaining a denser covering; but the best result is obtained by transforming the silver into a colouring matter absorbing compound and subsequently soaking the plate in a solution of an appropriate dyeing substance. Such a dye-absorbing substance is—as is well known—silver iodide; but it has been proved that silver sulphocyanide and colourless cuprous salts (cuprous iodide and cuprous sulphocyanide) are suitable for this purpose.

Some solutions for producing intensely coloured pictures from weak silver pictures are given below by way of example.

10 per cent. solution of potassium citrate...	40 c.c.s.
80 per cent. solution of cupric sulphate	15 c.c.s.
10 per cent. solution of potassium thiocarbamide	15 c.c.s.
Acetic acid	2 c.c.s.

After bleaching in this solution the plate is washed and is then dyed in basic dyes or certain acid-dyes (Säurerhodamin, Lichtgrün, etc.), whereafter the plate is again washed until the non-fixed dye has been washed out.

The plate may also be bleached in the known manner by cupric sulphate and potassium bromide, whereby the silver is replaced by silver bromide and cuprous bromide. These compounds do

not strongly absorb colour substance, but if the plate is afterwards treated with a solution composed of

Water ..	30 c.c.s.
10 per cent. solution of potassium citrate ...	20 c.c.s.
20 per cent. solution of potassium iodide ...	20 c.c.s.

in which is dissolved a little dyeing substance, for instance rhodamine, the plate is cleared and at the same time the dyeing substance is bound in the places previously occupied by silver bromide and cuprous sulphocyanide.

In the above example the potassium citrate may be replaced by other substances which have a hardening influence on the gelatine.

The above-described plate with silver bromide and cuprous bromide, or a plate with silver bromide only, may also be treated with a solution the essential compound of which is thiocarbamide, whereby dye-absorbing substances are produced. For instance, cuprous iodide may be dissolved in thiocarbamide and the plate be treated with this solution; or the following solution can be used which is especially adapted for the treatment when the film contains silver bromide or some other silver halide:—

Water	75 c.c.s.
5 per cent. solution of potassium metabisulphite	25 c.c.s.
4 per cent. solution of thiocarbamide	25 c.c.s.
20 per cent. solution of potassium iodide ...	10 c.c.s.
10 per cent. potassium sulphocyanide.....	25 c.c.s.

After treatment with one of the thiocarbamide-containing solutions the picture is dyed and washed out.

In any of these ways an intensely coloured picture is obtained which in the ordinary manner can be used for copying or which can form one of the three pictures in three-colour photography. The photographic films being more transparent, such films may be superposed during the photographing, and in this way all the negatives can be illuminated together without perceptible loss of sharpness.

In producing two-colour pictures according to this method the two differently sensitised photographic films may be arranged one on each side of the same film.

In producing three-colour pictures one film may be on celluloid, glass or the like and used in connection with the above-named double film.

Between and in front of the various films suitable screens can be arranged if necessary.

It has been proposed to add from 5 to 10 per cent. of silver bromide emulsion to the bichromated mucilages used for surfacing photographic plates and the like, to colour the almost invisible undeveloped image on such plates by means of dyes, the silver bromide being removed by a suitable solvent, and to use coloured positives produced in this manner for the three-colour process of producing coloured photographs.

It has also been proposed in sulphide-toning photographic silver prints to convert the silver salt into a halide by means of an alkaline solution containing potassium ferricyanide, potassium bromide, and thio-urea or a homologue thereof.—Jens Herman Christensen, Gollerod, Holte, Denmark.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

NILTONA.—No. 384,284. Photographic sensitised paper. Paget Prize Plate Co., Limited, 132, St. Albans Road, Watford; photographic plate and paper manufacturers. July 12, 1918.

LUXURIA.—No. 384,285.—Photographic sensitised paper. Paget Prize Plate Co., Limited, 132, St. Albans Road, Watford; photographic plate and paper manufacturers. July 12, 1918.

KRUPPS TO MAKE CAMERAS.—According to the "Daily Mail's" Berlin correspondent, the "Deutsche Allgemeine Zeitung" reports from Essen that the firm of Krupp will convert part of their great munition factory to the production of photographic apparatus, having reached an agreement with the Dresden firm of Ernemann.

Extracts from our weekly and monthly contemporaries.

The Lens and Straight Pictorial Photography.

WHY I advocate (writes "Flambeau" in the "Photographic Journal of America") only straight methods is that I am anxious to see photography attain an unquestioned place among the arts. This has been denied to her in most quarters, and only grudgingly accorded her in others. It looks to me that unless photography—which is painting by light is done entirely with a lens, and if brush-work is resorted to instead, or in part, the sponsors for that deviation are furnishing their opponents with all the reason they require to win their case. For where lens-work ends photography ends as an art (except for the chemical treatment necessary to develop the image and print, both impressed by light), and where other media are used to help out there is a confession of artistic failure in photography. With a soft-focus lens, in hands educated to its use, the entire work can be done by pure, straight, unaided photography, and so easily and well as to convince almost every unprejudiced person that she has attained to artistic rank of no mean order and cannot be displaced.

New Books.

RARE BOOKS.—The catalogues of rare books on the various branches of science and technology which are issued by Messrs. Henry Sotheran and Co., 140, Strand, London, W.C.2, are rightly appreciated by bookmen and bibliophiles for their detailed specification of volumes which are long out of print as well as for the very admirable classification and alphabetical arrangement of their contents. The list, No. 773, just issued, price 2s. 6d., is a volume of over 250 pages, which will repay the study of anyone interested in past technical and scientific literature. Photography, which is included in chemical technology, figures in the list only to a small extent, but Messrs. Sotheran have two copies of the work by Charles Louis Chevalier on cameras issued in 1829, and of great photographic interest through the association of Chevalier and Daguerre. They have also a copy of the "Guide du Photographe" by the same author, issued in 1854, and containing much information on the work of Niépce and Daguerre, and on the photographic processes which had come into use among French experimenters up to that date. The compilers of the catalogue do not spare criticism of photo-mechanical methods of reproduction in their comment upon the early work of Sampson on the making of engraved blocks. They say: "From it sprang in time the whole fell tribe of process blocks, which have starved out a beautiful art, set New Grubb Street writing up to blocks, and made each new and pushful publisher a terror to the tasteful."

THE CONDENSED CHEMICAL DICTIONARY.—A reference work on the chemical substances, natural and manufactured, which are commercially sold is newly issued by the Chemical Catalogue Company, 1, Madison Avenue, New York, price five dollars. It is a dictionary of chemicals, each entry in which states in a very readable form the chief properties and other particulars of commercial or technical interest. The compilation has been made with the aim of providing merchants, shippers, and dealers, rather than technical or scientific chemists, with information which is constantly being wanted in reference to chemical products. Thus each entry first states the colour and other physical appearance of the substance. Then follow data of such constants as specific gravity, melting point, and boiling point. A qualitative indication is given of solubility in water, alcohol, and ether. Brief particulars are stated as to the method of manufacture and the commercial grades in which the product is supplied. The entry further specifies the description of container in which the product can be packed, the chief uses to which it is put, and, lastly, gives similarly brief notes on the classification of the substance by fire-insurance companies, and on the shipping regulations applied to it by railway companies in the United States. A specimen entry will show the mode of treatment thus applied to each chemical:—

Sodium Sulphite: (a) Na_2SO_3 ; (b) $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$.

Colour and properties: White crystals or powder; saline, sulphurous taste.

Constants: Specific gravity, 2.6334; (b) 1.5939; melting point, (a) 150 degs. C.; (b) loses $\text{7H}_2\text{O}$ at 150 degs. C.; boiling point, (a) decomposes; (b) decomposes.

Soluble in water; insoluble in alcohol.

Derivation: Large sodium carbonate crystals are placed in a lead-lined vat on a perforated false bottom, a current of sulphur dioxide is passed up through the crystals; a solution of so-called sodium di-sulphite collects in the bottom of the vat.

This is saturated with sodium carbonate, concentrated, and allowed to crystallise.

Method of purification: Recrystallisation.

Impurities: Heavy metals; arsenic.

Grades: Pure, crystal, or dried; reagent, crystal or dried; commercial and B.P.

Containers: Wooden kegs.

Uses: Photography; preservative; antiseptic; reducing agent; medicine.

Fire hazard: None.

Railroad shipping regulations: None.

From this example it will be seen that the information in the volume is of a kind which is not readily ascertainable from the usual chemical dictionaries or text-books, or, at any rate, is discoverable in these latter only with a good deal more trouble than in a compilation such as the present one. The volume is certainly a most valuable addition to technical and commercial chemical literature.

New Apparatus, &c.

The Salex Studio Camera. Sold by the City Sale and Exchange, 81, Aldersgate Street, London, E.C.1.

ONE of these studio cameras, which are obtainable through any of the branches of the City Sale and Exchange, has been sent to us for our examination and review. Although moderately priced, the apparatus embodies the full range of movements which are of service in studio portraiture. In the half-plate model, which is the size we have inspected, the extension available from focussing screen to lens panel is 28 inches. There is double-swing movement of the back, each movement being separately controlled by milled set screws, and the front is provided with ample rise and fall, and with a lens panel 5 x 6 inches, sufficing to accommodate a portrait objective of ample focal length. The camera back is fitted with hinged focussing screen, and with detachable masks for postcard and panel ($2\frac{1}{2} \times 3\frac{1}{2}$) portraits. There are two single plate-holders,

one taking two postcard plates side by side and two panel portraits on a postcard, and the other fitted with carriers of postcard, 5 x 4, and quarter-plate sizes, and for the making of three panel portraits on a postcard plate. Both camera and plate-holders are very solidly and substantially made in dull satin-finish polished mahogany, presenting a very handsome appearance. In the half-plate size the price of the outfit, including two plate-holders, is £12. The postcard outfit is supplied at the same price, whilst in whole-plate size the outfit costs £15. Single plate-holders, in any of these three sizes, £1 17s. 6d. each. The outfit is certainly one which can be recommended to the beginner in studio portraiture who must limit his expenditure yet does not wish to buy a camera which is deficient in essential working features.

CATALOGUES AND TRADE NOTICES.

THE LANTERN SEASON.—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.4, have just issued a 96-page price-list descriptive of their many specialities for the winter season. These are chiefly optical lanterns and accessories for these latter in the shape of arc lamps, projection screens, and lantern slides, but the list includes also the Butcher series of enlarging apparatus, and further devotes a number of pages to the sets of model engineering parts, now so popular as an educational toy for boys, and supplied by Messrs. Butcher in great variety.

CITY SALE LANTERN SLIDES.—The City Sale and Exchange, 81, Aldersgate Street, London, E.C., sends us a 68-page catalogue of lantern slides, which are available for hire at odd times or regularly, according to a subscription system. In connection with this latter the firm makes a special offer to lend customers subscribing for the hire of 1,000 or more slides a lantern which is returnable at the end of the season. Deposit is paid on the lantern, and the amount is returnable, less a moderate deduction, when the lantern is returned immediately after Easter next. Particulars of this offer are obtainable in a circular just issued by the City Sale and Exchange.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MORNING, NOVEMBER 3.

South London Photographic Society. "Apparatus and its Use." W. J. Shields.
Dewsbury Photographic Society. "Printing Processes." A. Dordan Pyke.
Willesden Photographic Society. "The Domestic Fly; Life History, Structure, and its Menace to Health." Dr. O. H. Rodman.
Manchester Amateur Photographic Society. Print and slide entries for the Annual Exhibition.
Bradford Photographic Society. "A Journey to Mexico and the Far West." L. Whitehead.

THURSDAY, NOVEMBER 4.

Royal Photographic Society. "Demonstration of Raydex." F. R. Newens.
Hackney Photographic Society. Prints and Slides from 1919 Outings.
Chelsea Photographic Society. "Bromoil." G. B. Clifton.

WEDNESDAY, NOVEMBER 5.

Royal Photographic Society. "The Marshall Islands." T. J. McMahon.
Croydon Camera Club. The Annual Club Dinner.
North Middlesex Photographic Society. "Colour Plates." F. P. Bayne. Outing Print Competition—South Wimms.
Edinburgh Photographic Society. General Meeting. "X-Rays and X-Ray Photography." Dr. Hope Fowler, F.R.C.P.E.
Dennistown Amateur Photographic Association. "Transferotype Demonstration." W. W. Weir.
Partick Camera Club. Whisk Drive.
South Suburban Photographic Society. "Lantern-Slide Making." H. D. Freiwell.

THURSDAY, NOVEMBER 6.

Liverpool Amateur Photographic Association. "Local Prehistoric and Old Wrought Stonework." J. O. Creswell.

Hall Photographic Society. "A Holiday in Hull and Oxford." J. V. Saunders.

FRIDAY, NOVEMBER 7.

Royal Photographic Society. "Some Things Seen in Holland." W. Rawlings.
Dennistown Amateur Photographic Association. "Plates and Exposure." D. M'Millan.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held at 35, Russell Square, on Thursday, October 23, 1919. Present: Angus Basil, Gordon Chase, Alex Corbett, Alfred Ellis, S. H. Fry, W. E. Gray, Reginald Haines, Geo. Hana, Lang Sims, H. St. George, R. N. Speaight (London members), and Marcus Adams (Reading). Letters of regret for non-attendance were read from W. Illingworth (Northampton) and Tom Chidley (Chester).

The report of the Finance Committee was received, and its recommendation to continue the present Honorary Secretary as paid Secretary for the year ending December 31, 1920, was adopted unanimously. The Hon. Secretary was instructed to write to the gentlemen who had answered the Council's advertisement.

After discussion the Hon. Secretary was instructed to call a meeting of the Finance Committee to precede each Council meeting by half an hour.

The Hon. Secretary informed the Council that he had received notice from a member, Mr. Robert H. Rice, of Walthamstow, that he had lodged a complaint of the price of bromide postcards with the Holborn Local Profiteering Committee. He had also lodged a

similar complaint with the Cheshunt Urban Council as he was not sure whether he should proceed in his own district or in that of the business firm against whom the complaint was made. The complaint was worded as follows:—

To the Holborn Council Profiteering Tribunal.

Dear Sirs,—I am enclosing a quotation from Messrs. Houghtons, Ltd., of 88-89, High Holborn, W.C., photographic apparatus manufacturers and sundriesmen, for 20,000 bromide postcards at 65s. per 1,000, the ruling price in 1914 being 16s. per 1,000; this, in my opinion, being a flagrant breach of the Act, in so far as the price of bromide papers (which is substantively the same) has only been increased 75 per cent., viz., a gross of bromide paper 4½ in. x 6 in., costing in 1914 10s., as against 17s. 3d. for the same now.

Yours faithfully,

(Signed) ROBERT H. RICE.

P.S.—Not being sure of the proper procedure, I have also lodged a similar complaint with the Cheshunt Urban District Council Profiteering Tribunal.

After discussion the Council resolved unanimously to give Mr. Rice the full support of the Association, and instructed the Hon. Secretary to write him to that effect.

Mr. Corbett stated that he believed the Belgian and French manufacturers were acting in strict accord with English manufacturers in this "price" matter.

Mr. Arthur Brooks having reported that the preliminary arrangements for the holding of a photographic fair at the Horticultural Hall in April, 1920, were now completed, it was unanimously resolved that the Council hold a Congress in 1920.

A member having complained of the bad quality of dry-mounting tissue supplied by a London firm, and several members of the Council stating that they had also been supplied with unsatisfactory material from the same source, and the firm in question having refused either to exchange the defective material, or to return the price paid, the Council approved the Hon. Secretary's action in placing the matter in the hands of the Association's solicitor for legal process.

The next meeting of the Council will be held on Friday, November 14, at 6 p.m. (Finance Committee at 5.30).

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, October 23, Mr. T. H. B. Scott in the chair.

Mr. A. H. Blake delivered a lecture, with lantern illustrations, on "The King's Highway," a discourse on the evolution of roads in England from the earliest times. Mr. Blake pointed to the traces still remaining of the roads used by the early Britons, which were generally to be found along the sides of the hills and of which a good example could be traced between Lowes and Brighton. He passed to consider the roads made by the Romans, illustrating his remarks by photographs of the Watling Street and other examples of the highways constructed by the Romans. Coming to a later period, he dealt with the life of the road in the pedestrian time of the Canterbury Pilgrimages, illustrating the scenes of that age by reproductions of old drawings. The growth of wheeled vehicles on the roadways and the development of this form of locomotion to its culminating point in the stage coach services were followed in a series of interesting pictures. The desertion of the road caused by the development of railway lines represented a gap in Mr. Blake's subject, but in his discourse he came at last to the re-discovery of travel by road through the introduction of the motor-car. The lecture, in its blend of old and new, greatly interested a large audience, by whom a hearty vote of thanks was accorded to the lecturer.

CROYDON CAMERA CLUB.

Mr. A. DORDAN PYKE, representing Messrs. Johnson and Sons, gave a lecture on "The Art of Developing," essentially a lecture of real value to beginners, and avowedly intended for their benefit. It should also be added that the "trade" aspect was reduced to the minimum, too much so, perhaps, as all amateur photographers worthy of the name must naturally be keenly interested in the products of such a well-known firm as he represents. Mr. Pyke has a happy colloquial style, does not worry his audience with undue profundity, and last week, backed with a 20-oz. measure filled with pure cold water for sustenance, with the happiest smile in the world rushed

into the jaws of death by disposing of highly contentious points with a placid assurance one way or another, though warned in advance by the President (Mr. John Keane) that hoary-headed sinners were present on the look out for a cannibal repast.

The lecturer started by saying he had fairly got the wind up, for Croydon was one of the two last of a number of demonstrations recently given by him, and time after time he had been asked: "Have you appeared at Croydon?" and on the journey down disturbing recollections of these questions would persist in arising. It is quite impossible to follow him through his contribution, which naturally covered much old ground. Therefore only a few points can be alluded to. He started with the not unreasonable assumption that a camera and lens are necessary for the production of a negative of any sort, adding that perfect negatives were by no means easy to secure. Meters were very useful for determining the right exposure, but should never be allowed to become the master instead of the slave. There was no salvation in any particular plate or developer, and as regards the former, notwithstanding Mr. Sinclair's dictum to the contrary, he strongly advised the use of one of medium rapidity for all work, including snapshots, by the beginner. He advocated the system of development by time and temperature (Messrs. Johnson issue a very convenient chart giving the varying periods of development set against different temperatures), and exhibited a most workmanlike tank. On one occasion he had set out on a photographic trip armed with seven different makes of plates of medium speed, and all came up right in the tank. No white light should be allowed to reach the plate before it was fixed, though some had contended the contrary. For all-round use he strongly recommended the persulphate reducer. (Sensation.)

In the discussion Mr. A. F. Catherine was appalled, horror struck, and amazed at the recommendation of the persulphate reducer for beginners, which he had found most unreliable. In any case, it was the wrong reducer to employ with over-exposed negatives. "It was exclusively used in the R.A.F. Photo Section," said the lecturer. "And yet we won the war!" replied Mr. Catherine, looking more astounded than ever. Mr. J. M. Sellers shared the last speaker's opinion regarding the persulphate beast, and recommended the permanganate reducer. Mr. Vivian Jobling settled the point regarding white light being allowed to fall on the plate before fixation by saying he agreed with the lecturer. In such a case trouble might be met with in any attempt to intensify it. Mr. E. A. Salt followed at some length, regretting an hour was not at disposal to deal adequately with the contentious matter raised. The only really safe way to use the persulphate reducer was to make up a weak solution with hard water, and on the first signs of milkiness to withdraw the plate and wash for at least one minute. Any subsequent immersions in the reducer should be very short, and followed in each case by washing, with a final bath of sulphite of soda. Working in this way was slow but sure. In reference to some remarks made about the ferricyanide reducer and others having similar qualities, some correspondence had recently appeared in the "B.J." One important factor had, however, been overlooked, viz., the type of negative being dealt with. In the case of a fully exposed and developed negative, shadow detail might be composed of, and surrounded by, a very appreciable deposit of silver, permitting of a liberal application of a strong ferricyanide reducer. On the other hand, in the case of a negative with shadow detail set in clear gelatine, a similar application might mean its instant obliteration.

A most hearty vote of thanks was accorded Mr. Pyke for a capital lecture-demonstration. The very large audience showed the interest taken in the subject.

ROSS LENSES.—Messrs. Ross, Ltd., inform us that it is with great reluctance that they have to announce an increase in the price of all their photographic lenses of 25 per cent., dating from November 1. This increase thus corresponds with one of 66.6 per cent. on pre-war prices. Messrs. Ross add that when the previous increase of 33.3 per cent. was made it was hoped that by means of mass production and an early reduction in the prices of material to avoid a further increase of price and ultimately to manufacture at a reasonable profit. These hopes, unfortunately, have not been realised, and the further increase has been dictated as a measure of absolute necessity.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given that the partnership between William Davis and Joseph Willing, carrying on business as photographic agents at 173, Fleet Street, London, under the style of the General Art and Photographic Agency, has been dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by William Davis, who will continue to carry on the business in his own name or otherwise.

A receiving order has been made on a creditor's petition in the case of Richard Cardwell Barron, photographer, 7, Queen Street, Bloomsbury, W.C.1, and lately carrying on business at 19, Cheap-side, E.C.2, and lately residing at Shedfield, Ashley Road, Thames Ditton, Surrey.

A supplemental dividend of 1s. 1½d. in the £ has been made in the case of Arthur Aquila Noakes, photographer, residing and carrying on business at 17, St. Peter's Street, Canterbury, and lately carrying on business at 29a, St. Margaret's Street, Canterbury. The dividend is payable at the Official Receiver's Office, 68a, Castle Street, Canterbury.

NEW COMPANIES.

CLAN, LTD.—This private company was registered on October 20 with a capital of £500 in £1 shares. Objects: To carry on the business of manufacturers of, dealers in and agents for optical and photographic goods, etc. The subscribers (each with 250 shares) are: A. McConachie, 40, Milward Crescent, Hastings, pharmacist and chemist; Mrs. C. M. McConachie, 40, Milward Crescent, Hastings. The first directors are: A. McConachie (managing director and secretary) and Mrs. C. M. McConachie (both permanent). Registered office: 43, Plymlymmon Road, Hastings.

Correspondence.

FRADELLE AND YOUNG'S FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—Allow me to correct a statement in the article by "Practicus" in your issue of October 24, 1919. He says, "One of the best known flashlight workers, Mr. Fradelle, would never use explosive mixtures, etc." As a matter of fact, Mr. Fradelle was not a flashlight worker at all. I doubt if ever he made a dozen flashlight negatives in his whole career. It was his partner, Mr. Albert Young, who was the flashlight worker, and probably has taken more flashlight photographs than any man that has ever lived. I am in a position to know these facts as I was principal flashlight operator to the firm of Fradelle and Young for some considerable time, and Mr. Young and myself did all the operating.—Yours faithfully,

61, Biggin Street, Dover.

BERTRAM T. HEWSON.

A PHOTOGRAPHERS' CLUB FOR LIVERPOOL.

To the Editors.

Gentlemen,—Some time ago you were good enough to publish for me a letter on the above subject. While the responses were not numerous, it was gratifying to find that at least a few photographers take a live interest in their work and welfare. The club is still only a theory, but we are confident of ultimately achieving something.

In the meantime we are enjoying the social benefits of a local club—the Everton C.C.—which has offered membership to professionals. Any professional in or near Liverpool who can enjoy a good demonstration or a social evening should drop me a line, or communicate with the secretary, Mr. George Taylor, 11, Chapel Road, Anfield.

Letters from professionals outside Liverpool who are interested in the movement will also be welcomed by me. The Everton C.C. meets every Wednesday, at 8 p.m., at 14, Village Street.—Yours sincerely,

J. RONSON HALL.

55, African Chambers, Oldhall Street, Liverpool, Oct. 27, 1919.

SENSITISING CANVAS.

To the Editors.

Gentlemen,—A reader having written to me through yourselves asking for a process similar to that described in my letter in the "B.J." of October 10, but giving a silvery grey tone, I may add a few notes.

The method given by me was worked out for canvas, and, as the sepia colour has always been deemed right for such work, no attempt has ever been made to alter it.

With regard to producing a silvery grey tone on canvas, the addition of a small quantity of a solution of gold chloride to the salting solution (calcium chloride in alcohol) will correct the sepia colour, and by following up the addition doubtless the desired grey may eventuate.

For producing grey tones on paper, first of all salt the paper in the following solution:—

Ordinary table salt	120 grs.
Gelatine	30 grs.
Water	20 ozs.

Soak the paper in this until thoroughly impregnated, then hang up to dry, and sensitise by brushing over with a 20-grain solution of silver nitrate acidified with nitric acid. Dry in the dark, or in a room lighted by ordinary artificial light. Print somewhat deeply under a thin negative, fix and tone in a diluted combined toning and fixing bath, following with immersion in a weak bath of plain hypo, 1 oz. to the pint.

Grey images may also be obtained on bromide paper from an average roll-film negative, exposing at least 3 ft. away from an ordinary incandescent light.

"OLD PHOTO"

THE ETERNAL QUESTION.

To the Editors.

Gentlemen,—Will you favour me with a space in your valuable columns to express to my brother workers my experience since my return to civilian life after four and a-half years' absence?

It is seven years since I wrote through your columns on the assistant question, but this time it will apply to the profession generally. On being demobilised I was eager to commence work, but my pre-war employer (like many others) had filled the vacancy through my volunteering in 1914. Looking through the "Vacant Situations" the outlook was very disappointing, because it appeared that the girl assistant had been brought on a level with the male assistant. The employers were inviting correspondence from "either sex." This brought to mind the pre-war methods of cheap labour, and it evidently still exists. I do not say women are not capable of doing the same as men, but there are certain departments in the profession in which they would look considerably out of place, besides being inefficient.

During the war the girls have had a splendid opportunity to secure an all-round experience (at our expense), and it appears that in future they will be keen competitors in the labour market.

All over the country you will see an increasing number of women opening businesses on their own. I am not against them showing their independence; but it will mean a great deal to their sisters in this respect—the trade will be over-crowded, and the man who, on his return, contemplated a business of his own and combining marriage with it, will find he will have to give up the idea of the latter or change his job. I am not suggesting that the man will be afraid of competition in work; far from it, from what I have seen of the exhibitions of some of their work; but there will not be the scope for so many photographers.

No one can dispute that girls can live more cheaply than men. Therefore they will be able to produce their work at lower prices, and also "offer" themselves at lower wages, thus throwing the men who left their situations to "defend their country and women-folk" on the unemployment lists.

Regarding the "cut-throat" scheme that goes on in respect to the applications for a situation, take the advertisements in the vacancies, and you will scarcely find one employer who states what salary he is prepared to give. What is the result? Only this—that the hard-pushed fellows, just come back, are compelled to offer themselves cheap so as to secure a situation.

What is there against an employer stating the class of man he requires and the salary he is prepared to give? He can then choose a suitable man from his applicants by his specimens of work, etc.

Another point which will probably make some ashamed to be in such an underpaid profession. Take the average assistant or branch manager, who has put heart and soul into his work and studied it. What are his wages compared with a tram conductor who punches tickets? Fifty to sixty shillings is considered good for an assistant, and a slight commission for management, while the tramway men strike for sixty-five and get it. Don't forget, the tramway men are supplied with uniforms against the smart appearance the assistant is expected to keep up out of his "dibbs." Just look at the comparison between the two. One holds the great responsibility of dealing with penny tickets and has qualified himself so by "studying arithmetic," with some nice joy-rides into the bargain, while the other has studied items too numerous to mention, and is subject to mental exertion whatever he does, and in addition the P.P.A. want him to pass examinations in the case of management. He has pounds to deal with and a small staff to supervise, with other responsibilities, yet, according to the profession, he is not worth any more than the ticket puncher. I will repeat what I said in my letter seven years ago—that so long as assistants are underpaid they will be tempted to make up for it through dishonesty.

One more important fact which ought to be remedied, the question of Sunday work. Very often you don't know you have this to do until you are engaged and arrive at your place. Such is my present case; so, brothers, beware! and make this inquiry before final settlement. Now, why, like everybody else, are we not paid double time for Sunday duty? One full day a week does not compensate for the one and a-half days you get in a Sunday-closing business, let alone the shamefulness of working on the Sabbath.

Excuse me for occupying so much space, but I hope this letter will not prove fruitless, and that some good improvement may be made in the profession.—Yours faithfully,

"STILL HOPING."

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. A.—The greatest variety of filter dyes is now obtainable from the Pfzerd Co.

M. H.—If your business is done locally you require a licence, the office for which is Iddesleigh Mansions, Westminster, S.W.1.

J. B.—You require a licence, and should apply to the Secretary, New Businesses Licensing Order, Iddesleigh Mansions, London, S.W.1.

V. B.—There is no information which can be given to you other than that you write to the secretaries, whose names are published, for prospectuses and entry forms for the exhibitions.

A. F.—You can get the so-called gold-dust (imitation gold) from any of the dealers in artist's materials, such as Messrs. Reeves and Sons, 18, Ashwin Street, Dalston, or Roberson and Co., 99, Long Acre, W.C.2.

H. C.—The 21 cm. (8½ ins) lens had a pre-war price of £10, and should, we think, command that price, or even a pound or two more, at the present time to a direct purchaser. The lens was listed to cover a 7½ x 5 plate.

W. N.—We should prefer at least a 7-in. lens, particularly if an R.R.; but if your exposures are being made almost wholly at a small stop as *f* 22, probably a 6-in. R.R., such as a Beck rapid symmetrical, would be quite satisfactory. At that aperture there would be very little to choose between the definition and that from an anastigmat.

I. T.—The reasons you give for the unsuitability of your present lens, namely, the long time required in focussing and the necessity to use a swing-back, are not clear to us, but for a studio of your length the maximum focus for a full-length cabinet is 10 inches.

F. F.—There is no method of making enlargements transparent, but the paper can be rendered somewhat translucent by the usual methods of ironing in paraffin wax or impregnating by swabbing the enlargements with a mixture of castor oil and volatile solvent—for example, ether.

J. N.—We are sorry we cannot give you any advice of practical value without seeing the tablet. In the ordinary way we should use an oblique lighting, rather diffused, but much depends on the amount of relief in the letters and that of any ornament on the margins or elsewhere.

E. H.—The book "Tom Wedgwood, the First Photographer," by Litchfield, was published in 1903 by Duckworth and Co., 3, Henrietta Street, Covent Garden, W.C. "The Romance of Modern Photography," by Gibson, is supplied by our own publishers, price 5s. 6d. post free.

A. J. R.—The office to which to apply as regards the licence is the Retail Business (Licensing) Section, Ministry of Labour, St. Ermin's Hotel, S.W.1. If you do not trade under your own name, you will require to register. The office for this is 39, Russell Square, W.C.1. There are no other restrictions on starting a business of this kind.

S. C.—1 and 5. Yes, in both cases. The office is Retail Businesses (Licensing) Order, New Arts Building, Liverpool. There is no charge. 2 and 3. It is purely a question of what you consider to be honest. There is nothing to prevent you. 4. We suppose that if you put a picture in a frame which you buy you may call yourself a picture framer. Surely this is a question an answer to which is useless.

V. P.—A condenser lantern, however much the light is diffused, always shows retouching in the enlargement more than does a lantern in which the negative is illuminated by reflected light or from a very diffused light-source, such as daylight or mercury vapour. Opal glass is a much greater diffuser than ground glass, and will diminish the prominence of retouching to some extent. Exposure will be very much longer; it can easily be five or ten times longer.

L. T.—It is rather difficult to suggest a cause from a print which is so very little spotted. We doubt very much if the brown spots are due to iron in the washing water; they have more the appearance of metallic impurities in the paper base, and it is quite possible that if we saw other specimens of the spot there may be reason for thinking that air-bells during fixing had something to do with them. Apparently the best thing you can do is to filter your tap-water through a flannel bag. If the spots then disappear, well and good; but if they do not, you will have to look in other directions.

J. B.—1. A wholesale business does not come within the scope of the Retail Businesses Licensing Order. Photography of any kind, however, does come within the scope of the Order, and if this business is being newly established a licence will be required. The office for your district is Queen's College, Paradise Street, Birmingham. 2. Copper certainly is liable to form an explosive compound with acetylene, and usually connecting pipes are of solid tinned copper or of iron. 3. If you have some experience and aptitude, postal lessons will benefit you very greatly. A good teacher is Mr T. S. Bruce, 4, Villas-on-Heath, Vale, Hampstead, London, N.W.

J. G.—Yes, the projection lens on the enlarger should be one which covers a half-plate to the corners in the ordinary way. You do not say what the light-source is in the enlarger, but, presuming it is one of relatively small size, such as an incandescent gas-mantle or an electric arc, probably the Dallmeyer will be the better lens of the two because of its larger aperture. The larger aperture of lens with ordinary light-sources obviates in a measure the difficulties in getting even illumination on the ground. In the case of an extended light-source, such as an illuminating chamber or a mercury tube, there is very little to choose between the two lenses on the ground of aperture, except that, of course, exposures would be somewhat shorter with the Stigmatic.

D. H.—If made up in two solutions developer should keep fairly well for months at a time; but we have no special formulæ which we can recommend to you other than those of the White Band Manufacturing Company, Progress Works, Selsdon Road, South Croydon. If you have not their latest complete circular of instructions we suggest that it would be worth your while to send for it and at the same time to ask for information as to the formulæ which they find to keep the best.

W. L.—You do not tell us enough about the spots to enable us to do more than guess at the cause. If the light markings come up in development it is difficult to say what is the cause of them, but if they appear after prints have been fixed it seems possible that they may be due to drops of hypo solution lying on the prints. One or two of them have this appearance. The black spots may be due to dry developer dust or even dry particles of hypo settling on prints or paper before development. Unfortunately, you tell us so little about the stains that it is impossible to say more.

J. L.—There are two studio gas installations on the market, one or other of which will be much better for your purpose than any home designed or made apparatus. They are the "Howelite," of Messrs. John J. Griffin and Sons, Kemble Street, Kingsway, London, W.C.1, and the "Powerful," of Messrs. Kodak, Ltd., Kingsway, W.C.2. Exposures with an extra rapid plate and $f/4$ lens usually run into four or five seconds for half-lengths or bust portraits. A gas installation is hardly the best thing for groups, but quite successful work can be done if you can supplement gas with a little flash light.

AEROPLANE PHOTOGRAPHY.—A handbook on this subject is among the autumn announcements of the J. B. Lippincott Company. The author is Major H. E. Ives, the physicist son of Mr. F. E. Ives, who was actively connected with the United States Air Force Department.

THE SCOTTISH SALON.—Writing in reference to the notice of the forthcoming Scottish Salon, which appeared in last week's "B.J.," the Salon secretary, Mr. John Macdonald, makes a correction. The entry fee is two shillings per entrant, not for each entry form of eight pictures.

The British Journal of Photography.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

		ANSWERS TO CORRESPONDENTS	656

SUMMARY.

In a week's time—namely, on Friday next, November 14—the pages of the forthcoming "B.J. Almanac" must be closed as regards the receipt of advertisements.

In a contributed article "E. A. S." describes in detail a method of vignetting negatives which allows of extremely perfect adjustment of the vignetting mask to the subject, and is very easily and quickly carried out. Ordinary dry-mounting tissue is used as the material of the vignette. (P. 648.)

Mr. T. H. Greenall sends a warning as to the use of barium instead of sodium sulphide for sepia toning, and mentions how the instanced drawback of barium sulphide may be avoided. (P. 655.)

A scientific and technical Group has been formally established within the Royal Photographic Society. Some particulars of its aims and programme will be found on page 651.

In a leading article we refer to a somewhat remarkable case in which proofs were kept for as long as thirteen years before being returned to a studio. We endeavour to come to a conclusion as to the legal position of a photographer in such or similar circumstances as regards his liability for custody of the negatives and for delivery of the portraits. (P. 646.)

In his article this week, "Practicus" deals with the utility of lenses of the telephoto type in photography such as very frequently is required from professionals. The special feature of the telephoto lens is its provision of long equivalent focal length in conjunction with relatively short camera extension. (P. 647.)

Some of the things which may advisedly be done beforehand for the purpose of smoothing the rush of Christmas work are the subject of a contribution to "Assistants' Notes." (P. 651.)

For occasional purposes advantageous use can be made of localised sepia toning of bromide prints. (P. 645.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article Mr. R. M. Fanstone has some advice to give on the choice of apparatus for the Autochrome and Paget colour processes, his hints extending to the selection of camera, lenses, and plate-holders. (P. 41.)

Some further hints on the working of the Paget colour process are contained in paragraphs on page 44.

Some further very general particulars have been published of the process of colour photography of S. M. Prokudin-Gorsky, the first announcement of which was made some weeks ago. (P. 44.)

A recent patent specification contains particulars of an invention the aim of which appears to be to provide a sensitive material ready for use in the making of two-colour or three-colour sets of negatives. (P. 43.)

EX CATHEDRA.

To Society Secretaries. Yesterday the secretary of every photographic society, the name of which is on our books, should have received the form of application for particulars of his association to be published in the Directory of Photographic Societies in the forthcoming 1920 "Almanac." In some cases, owing to the unavoidable abandonment of their offices by secretaries during the war, this form has been addressed to the meeting place of the society in default of particulars of the name and address of the secretary. We would ask the secretary of every society to take the necessary steps to send in the particulars which are asked for with as little delay as possible. Also, we would intimate to any secretary who, at the time of reading this notice, has not received our application to address a post-card to us, asking for an entry form to be sent to him. We are anxious to make the first post-war list of photographic societies as complete as possible, and in view of the changes which the war imposed upon many societies, can only do this through the friendly and prompt assistance of those who are now responsible for the secretarial management of societies.

* * *

To-day Week. On behalf of our publishers we desire to notify all intending advertisers in the forthcoming "Almanac" that Friday in next week, November 14, is the latest day for the receipt of advertisements. The firms who have not yet signified their wishes in respect to advertisements in the forthcoming volume will receive during the next few days a notice of this final date. We hope, however, that the present intimation will serve the purpose of making this final reminder unnecessary, and in that aim we emphasise the present announcement to all those under whose notice it comes. Unfortunately, the contract arrangements for the printing and binding of the "Almanac" make any extension of the scheduled date for closing its pages quite impossible.

* * *

Local Toning of Bromides. Most people are aware that self-toning of collodion papers can be locally toned to a cool greyish tint by painting the parts which are intended to be of this colour with a strong solution of common salt before immersing the print in the usual fixing solution, but it has perhaps not suggested itself to many that it is easy to do the same thing with bromide prints, the only difference being that the brush-work is done upon the parts which are to be of a sepia tone, the image as developed furnishing the greys. All that has to be done is to apply the ordinary bleaching solution of ferricyanide and bromide to such parts as are to be toned, taking care to keep accurately to the outlines, and after washing, which should be done with a copious

supply from a rose, to immerse in the sulphide solution as usual. If by an accident the bleacher has gone beyond the proper limits the black colour can be restored by careful application of an amidol developer with a clean brush, and rinsing well before sulphiding. The process may not have any great value from an artistic point of view, but there are occasions on which it may be useful to be able to differentiate between different parts of a print by means of colour.

* * *

Copying Tables.

Although a copying stand of some kind is usually found in studios doing a general class of business it is often too small in its dimensions to be useful for large pictures. Much loss of time is caused when one of these has to be copied, as it is often found in using a detached camera and easel that after size and squaring up are satisfactory the whole arrangement has to be altered to avoid reflections, whereas if the whole were fixed upon a movable base it could be swung round until satisfactory lighting is secured. A very large copy board is not needed, as its only purpose with large-framed pictures is to keep them at right angles to the lens. The camera may be fixed upon a platform supported by uprights, similar to those of the Hana or Semicentennial studio stands. But though no elaborate mechanism is needed for raising and lowering it, it may be placed at approximately the right height before putting the camera upon it. We have lately seen such a stand made for a picture dealer for the use of any photographer he might employ, and it struck us that the idea was one worthy of general adoption.

* * *

Finishing Commercial Work.

The photographer who only occasionally undertakes commercial work is sometimes at a loss as to the best method of finishing unmounted prints, and in consequence his results are often disappointing when compared with the work of specialists. As a rule a glossy surface is preferred, and in this case a high degree of polish is necessary, nothing being less attractive than a print dried as it comes from the washing water. A good surface can be obtained by squeegeeing down upon ferrotype plates, and these require no treatment except an occasional rub with a soft rag moistened with a few drops of kerosene, afterwards polishing until all trace of bloom is removed from the surface. There is much less risk of "sticking" with ferrotype than there is with glass, but more care is needed to keep the surfaces free from scratches. These may be avoided by keeping the plates between blotting paper when not actually in use. Prints may easily be mounted upon linen or tracing cloth by means of the ordinary shellac tissue, this style being very suitable when the prints are required for travellers or showroom use. When card mounts are used, glossy prints should always be dry-mounted, as the gloss is perfectly retained. It is a little more costly than wet mounting, but the improved appearance will justify charging a little better price.

* * *

Large Prints and Exposure

We are generally told that large heads require more exposure than half or full-lengths taken with the same lens used with the same stop. This is usually understood to be in consequence of the working aperture being reduced by the addition to the back conjugate focal length in consequence of the near approach to the sitter, but there is an additional reason, which is that the area of any ungraduated patch of either light or shadow is greater in the large image than in the smaller one, and, therefore, if viewed from the same distance the former will appear harder and less exposed. This condition, of course, obtains in enlargements from small

negatives, but as these are usually viewed at a greater distance it is not so apparent. It is, however, recognised, for it is agreed that the ideal negative for enlargement is one more fully exposed and not developed to the same degree of density as one which is intended for contact printing. For the same reason large negatives are often printed upon distinctly rough paper, the grain of which helps to break up such ungraduated patches. One has only to compare prints (from a rather hard 15 × 12 negative) upon glossy P.O.P. with those on rough bromide or platinum paper to see how far this is the case.

UNRETURNED PROOFS AND THE PHOTOGRAPHER'S LIABILITY AS TO THE NEGATIVES.

THE business of photographic portraiture has its own special small problems, of which, in the course of a somewhat lengthy experience, we imagined that we had considered at one time or another all the possible variations. Nevertheless, a particular case recently brought to our notice by a correspondent raises a point which we cannot remember having previously arisen, either in a court of law or otherwise. It may be useful to refer to it since, apart from its particular circumstances, it raises a question which is not by any means as well defined as it might be. Briefly, the facts stated by our correspondent are as follows: Four years ago he took over a photographic studio from the previous proprietor, the studio having been established a number of years prior to this transfer. Within the last few days he received from a lady a batch of untoned proofs of portraits taken thirteen years ago, and for which payment had been made at the time of the sitting, the proofs being accompanied by a request for delivery of the photographs. It appears that in the meantime the sitter, the son of the present applicant, had died, and the mother had therefore a special reason for wishing for the photographs. Our correspondent, however, has no knowledge of the existence of the negatives, has never seen them, and can find no record of them in his files. The question thus arises: What is his liability in respect to the order given, to a predecessor of his, nine years before he took over the business, and dormant for the long period of thirteen years?

In seeking to give an answer to the question we can only be guided by what would probably be the view of a court, for, so far as we know, no case in which the circumstances correspond with those we have mentioned has been the subject of legal action. One thing, at any rate, is clear at the outset, and that is that if anybody is liable for custody of the negative and delivery of the portraits, it is the present proprietor of the business. In acquiring the latter from the previous owner he took over both its assets and liabilities, even though the number and magnitude of both of these were not disclosed to him. But the chief question is whether anyone is now liable in respect to the custody of the negatives? On this general question there are, unfortunately, very few judgments from which to derive guidance. From such cases which have come into the courts, most of them in the comparatively early days of photography, it was clearly established that the right to the custody of the negative is the photographer's, but we cannot call to our recollection any equally definite ruling as to the sitter's right that a photographer should take due and sufficient care of a negative for the purpose of using it on further occasions as the sitter might direct. In view of the ease with which a fresh negative can be made from an existing photograph, it is not surprising that there should have been no cases on this point in the court, yet we doubt very much if a photographer's customer could demand as a legal

right the preservation of the negative throughout an indefinite period, for the problematical contingency of re-orders from it by the customer. If that is the case, and in our lay opinion it is, then we think it follows that in the circumstances set forth by our correspondent there is even less ground for supposing that the negatives should have been kept, and that the photographer is breaking a contract with his customer by having allowed the negatives to be lost. It seems to us that in such circumstances as these the photographer may be presumed to have done all that he could to have executed the order. The negatives were taken, proofs sent, and the portraits unquestionably would have been delivered if anything more had been heard of the proofs. We do not profess to have a professional knowledge of the various Statutes of Limitation, yet we think that an effluxion of time of thirteen years between the sending and the return of proofs deprives the customer of the

right to take legal action in respect to the delivery of the photographs or the return of the money paid for them. It would be the same if the circumstances were in a measure reversed, and the photographer, after a similar lapse of time, were endeavouring to recover from the customer money which he would charge for a sitting, even though, from one cause or another, the actual portraits were not delivered. In other words, the problem which our correspondent has presented to us is not, we think, affected by the question of whether payment was or was not made at the time of the sitting. In these notes we have, of course, regarded the present applicant to our correspondent as possessing any rights which the original customer possessed, or imagined he possessed, at the time of his death. That raises considerations of an altogether different kind, which are, however, without relevance to the particular problem we have been considering.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).

TELEPHOTO LENSES FOR PROFESSIONAL WORK.

As a body professional photographers do not seem to have taken very kindly to telephoto lenses, evidently considering them only fit for amateur "stunts," such as making large pictures of clock dials and weathercocks at a distance of half a mile or so. This feeling has, I believe, been created to a great extent by the specimen pictures published by the lens makers, who are naturally anxious to demonstrate to the utmost the capabilities of their instruments. It will perhaps help the professional to a better understanding of the telephoto lens if we consider it as an ordinary lens of greater focal length than usual, but needing only ordinary camera extensions—a lens, too, of which the focal length is adjustable, so that images on different scales may be obtained from the same standpoint. It will then be recognised that such a lens is a valuable tool in the hands of a practical man.

As many photographers have never troubled their heads about this kind of lens, it may be necessary to explain that in its simplest form it closely resembles one tube of an ordinary opera-glass—that is to say, it has a positive lens in front and a negative lens behind, with some arrangement for vary-

ing the distance between them. As a matter of fact, although not properly corrected for photography, it is possible to make very passable telephotographs with an opera-glass fixed on an ordinary camera. There is rather a large variety of sizes and models issued by different optical firms, but they may roughly be divided into three classes: First, non-adjustable—i.e., fixed focal length telephoto lenses, such as the Telecentric and Bistellar; second, telephoto lenses with an adjustment for varying the focal length, such as the Zeiss Magnar, Dallmeyer Adon, and others; and, third, portrait, rapid rectilinear, and anastigmat lenses, fitted with a telephoto attachment, which can be screwed on in a moment, when needed, without at other times interfering with the usual work of the lens.

The first class is usually of low magnifying power, and differs little from an ordinary lens in its manipulation. It is extensively used on reflex and other cameras for rapid exposures, and in some cases the large aperture ($f/5.6$) permits of portraiture in the studio. It should be noted that, in common with all telephoto lenses, the plate covered is small in relation to the focal length used.

The second class is useful for a wider range of subjects when rapidity of action is not essential. The little Adon is a well-known example of this type, and although simple in construction, is capable of much useful work. I therefore take it as a type to illustrate the working of telephoto lenses in general. The front or positive lens has a focal length of $4\frac{1}{2}$ ins., and the back lens a negative or minus focus of $2\frac{1}{4}$ ins. By varying the distance between these by means of the rack adjustment we have a wide range of focal lengths. Thus with a camera extension of 5 ins. we have an equivalent focal length of $14\frac{1}{2}$ ins. and a maximum aperture of $f/13$, the plate covered being $4\frac{1}{2} \times 3\frac{1}{4}$. At 11 ins. camera extension the focal length is $26\frac{1}{2}$ ins., the aperture $f/26$, and the plate covered about 8×6 . At 20 ins. extension the focal length is $44\frac{1}{2}$ ins., the aperture $f/44$, and the plate covered 15×12 . These figures give a general idea of what a moderate-power telephoto lens will do.

The third class is usually of somewhat similar power to the Adon, as it commonly consists of a combination of a positive lens of any convenient focal length, with a negative lens of half its focal length, although for special work negative lenses having a focal length one-fourth that of the positive may be used. Such a combination is termed a high-power lens, as it gives a proportionately larger image with the same camera extension. I am purposely avoiding the term "magnifications," as this I consider has led to misunderstanding in the past. The equivalent focal length at the time of exposure is the point of interest to the photographer who does not care whether it results from three magnifications as compared with one lens or six with another.

The manipulation of a telephoto lens is quite simple, and the only difference from the ordinary procedure is that focusing is best effected by using the rack and pinion of the lens attachment instead of that of the camera. With a moderate-power attachment—that is to say, one-half the focal length of the positive—the equivalent focal length is twice the camera extension (measured from the back surface of the negative lens), plus the focal length of the positive lens. Thus, when using an 8-in. rectilinear fitted with a 4-in. negative lens, we have at an extension of 16 ins. an equivalent focal length of 40 ins., and so on for all other sizes. The focal length in this case being increased five-fold, the $f/\text{No.}$ on the iris must be multiplied five times, so that $f/8$ temporarily becomes $f/40$. Having decided upon the camera extension, all that is needed is to rack the sliding tube of the attachment in or out until a sharp image is obtained. This must be done very slowly, much in the same way as when using the coarse adjustment of a microscope, or there is danger of passing and re-passing the point of sharp definition without knowing it. It might be imagined that with apertures of $f/40$ or less long exposures would be required, but these are greatly reduced by another factor, the distance between lens and subject so that in many

cases half or even a quarter the exposure indicated by a meter for an object, say, at 36 ft., would be sufficient.

A colour-screen usually adds considerably to the brilliancy of the result when distant views have to be dealt with, but it is not necessary for near subjects in which there is no perceptible haze over the deepest shadows.

Plates which give density readily are the best for this class of work, and I have found the "ordinary" and slow ortho rapidities preferable to extra rapid brands. The Imperial Special Rapid is about the fastest plate I should recommend.

Development usually takes longer than for close-up views. A full-strength developer should be used and development carried on until all action ceases. I have turned a plate face down supported by four bits of glass in the corners in a normal pyro-soda solution, containing a little bromide solution to prevent chemical fog, and left it for forty-five minutes, the resulting negative being an excellent one.

The applications of the telephoto lens are many and varied, and cover a much wider field than is generally imagined. In ordinary view work its value is obvious as its elasticity of focal length enables a subject to be taken from the most advantageous standpoint upon any desired scale, so that the proper amount can be included upon any size of plate. For architectural details it is unrivalled, whether the result is a fine piece of carving for study or illustration, or a piece of faulty work, cracked or subsided for use in a legal action. When the London tubes were projected the houses under which the tunnels would pass were carefully surveyed and telephotographs taken of all existing cracks or distortions before commencing work. In quite another field of study photographs of statues scores of feet above the ground were taken for the purpose of identifying them as the work of the same artist, little mannerisms being clearly shown in the prints.

For catalogue work, especially of small articles which have to be depicted in their full size, or nearly so, the telephoto lens is again a winner. Let anyone compare a print of a snuff-box taken full size with, say, a 12-in. lens and a telephoto at 20 ins. camera extension. For flower photography the telephoto is excellent, much greater depth of definition being obtainable, while some lenses add a slight softness to the outlines which gives a better idea of the texture than the dead sharp images usually obtained.

For portraiture its use is somewhat limited on account of the small working aperture of most models, but the Telecentric makes an excellent portrait lens. Lenses upon the same principle are, I believe, to be placed upon the market by two other firms.

The foregoing is not in any way intended to give full working instructions, but rather to outline the properties and uses of the telephoto lens to those who have hitherto neglected it. Several excellent books have been issued on the subject, and these can be referred to for fuller information.

PRACTICUS.

A METHOD OF VIGNETTING FOR DAYLIGHT-PRINTING PAPERS.

THE following notes are primarily intended for the attention of any who experience trouble in vignetting. These, judging from results not infrequently seen, even in show-cases, where, presumably, the best work is displayed, are not in an altogether negligible minority. This proviso in advance is necessary, for the writer, more than once, has found that photographers who will gladly consider any general ideas new to them, are immediately up in arms when a suggestion is made with regard to vignetting, for the very sufficient reason that their particular method is invariably the best. Quite recently a professional

potentate from overseas, the president of important federations and so forth, and an extremely clever and artistic worker, absorbed with avidity some assorted tips, but froze several degrees below zero on the subject of vignettes. "Let me show you my way," he remarked, and in doing so recovered a genial temperature. His plan was the well-known expedient of covering the back of the negative with tissue-paper or papier minérale, and working thereon with blacklead and stump, the vignette being either a plain or serrated opening in brown-paper or thin card. With presentable negatives and printing

to daylight, and also with bromide papers and printing boxes, possibly the method is as good as can be wished for, and that being so, there was no reason why he should have considered an alternative.

Mercury Lamps and Vignettes.

But this worker, unlike the writer, was not working with mercury printing lamps, an ideal substitute for daylight, apart from vignetting, nor had he to cope with and make the best of a variety of negatives, including the apparently hopeless. With double-tube lamps, though they cannot compare with good daylight as regards diffusion, vignetting is still fairly easy, but with single-tube lamps, presenting as they do one bar of light, conditions are not so favourable, and it was to meet these that the method to be discussed was devised. It is one not new in its main principle, but in details—making all the difference as a practical proposition—it is believed novel.

Excellent diffusion with a single-tube lamp can, of course, be obtained by placing white tissue-paper over the opening in the vignette, but as this slows printing 50 per cent. and upwards, it is ruled out of court with dense negatives; also electric current costs money, economical as the lamps are in consumption of current.

It almost goes without saying that any method of vignetting that will work well with these lamps will answer even better with daylight.

The Pear-Shaped Vignette.

The various ways of vignetting recommended from time to time are outside the scope of these notes. Except the obviously unsuitable, most have been tried with the lamps, and none appear to possess sufficient flexibility or adaptability for negatives of widely different character and printing value.

The reign of the pear-shape vignette is almost over, and deservedly so, even if one has a sneaking and debased affection for it as a relic of the past. Assuredly, if its exponents had existed in the time of Noah, and an order had been placed for "head and shoulders" vignettes of the animals in the Ark, a portrait of the giraffe would have been printed under the orthodox vignette.

But the fundamental objection to this vignette is often found present in modified form in present-day vignette sketch portraits. Take the case of two heads fairly close together on one plate—how frequently does one see an ungraduated tint of medium depth between them marring the sketch effect. Or in the case of, say, a little boy with legs sturdily apart, a meaningless variation of depth in the background, sharply bounded on each side by his lower extremities.

Although some operators do wonders in improvising serrated vignettes out of those in stock, yet in the majority of cases the making of a vignette to suit each negative guarantees the best results and has invariably been adopted by the writer except with identical poses. During the war, when all had to turn their hands to the pumps, he made many hundreds, if not thousands, by the method now to be discussed.

Outline of Procedure.

An "improved" retouching desk is improvised out of a large picture frame set at a convenient angle by rigid struts, and is furnished with a reflector of white blotting paper. A regular retouching desk will not be found so handy. The negative is adjusted to the desk, glass side towards the operator, a piece of white tissue paper is placed over it, and a line is drawn right round the figure (assuming a "full-length" is being dealt with), about half-an-inch beyond it. This margin will naturally vary according to circumstances. A touch of gum is centrally applied to the other side of the tissue paper, which is stuck down on brown paper or thin card, and the vignette opening is cut out. A piece of adhesive dry-mounting tissue is placed over the opening, and caused to adhere by

touches of the hot iron. The embryo vignette is adjusted to the negative and centred, the outline of the figure is traced round with a sable brush, using dye in methylated spirits and spirit varnish as pigment. The negative is then slid on one side, and strokes, broadening as they progress, are made round the outline. Using a pen trimmer on zinc, the outline is cut out, and the vignette shown diagrammatically in fig. 1 results. The example represents one for a little boy.

Fig. 1.

This, of course, is a variant of the oft-suggested method of employing ordinary tissue paper and water-colour pigment to the same end, one open to several objections. With tissue paper, if the central part, representing the outline of the figure, is cut out, the edge usually is far too harsh; if left intact, printing is slowed unduly, and the vignette cannot be adjusted by inspection from the front. With the newer way, thin waxed paper has been found sufficient for diffusion. On the other hand, with very thin and quick-printing negatives, tissue paper or ground-glass should be employed.

Psychology.

"If the gov'nor caught me using adhesive tissue for vignettes, I should promptly get the sack," pleasantly observed an assistant, by way of testimonial, on being shown this method. Aforesaid "gov'nor" was employing platinotype papers printed to mercury light, and throw-outs due to faulty vignetting were by no means unknown.

Experience has shown that diverting the tissue to a use it was never designed for has materially cut down waste. Dealing with all sorts of negatives, good, bad, and indifferent, rarely is a first proof thrown out merely for faulty vignetting. The less expensive waxed paper may be substituted for the tissue if preferred, and for large vignettes will appeal. It is stuck down by small pieces of tissue interposed between it and the brown paper or card, the tissue being one of the few things that will stick waxed paper. In practice, pieces of the tissue cut from the smaller vignettes are saved, and employed for sticking the waxed paper utilised for the larger, and it may be mentioned that the thin and translucent tissue sold by the Adhesive Dry Mounting Co. alone has been used, though doubtless many other brands would be equally suitable.

Although hardly to the point, it may be added that stored packets of silver papers can be kept largely free from injurious atmospheric influences by wrapping them in one or two folders of waxed paper and then running round the edges a line of thick orange shellac varnish, which, when tacky, is sealed with the hot iron; or long strips of adhesive tissue can be employed instead. The folders should be larger than the packets of paper, so that the heat of the iron is not transmitted to their contents.

Some Suggestions.

Frequently a figure taken with a table or chair adjacent will be the better if these accessories are subordinated. In such cases the opening in the opaque paper or card is cut sufficiently large to include them, but the adhesive tissue is outlined strictly round the figure and cut out. Long and gently tapering strokes of the brush, placed close together, or otherwise, as occasion demands, will give softness, and additional pieces of the tissue, each piece in advance of the next, can sometimes be added with advantage.

Backgrounds which print unequally can be levelled-up by placing strokes close together over the parts of lesser density, and spacing more widely over the more opaque parts. Similarly, too heavy printing, say, on one side of a face or bust, can be lightened by advancing a piece of tissue, serrated, if necessary, over such parts. The frequent case of the legs of a child printing too heavily can be corrected by spanning the vignette with a bridge of tissue. If insufficient in holding-back power, dots of paint can be added. Even central portions printing too dark can be held back by dotting the diffuser of the vignette with paint, a method which gives wide control but necessitates a proof as a guide.

Following the figure round will sometimes produce peninsulas (as in fig. 1), which insist on drooping towards the glass of the negative. Take a piece of sewing cotton, pass under, and fasten at each end with an applied bit of the adhesive tissue. Or the drooping piece can be attached to the diffuser of the adjusted vignette, freeing one end and slipping a hand under, followed by a light touch of the iron.

Bust Vignettes.

A very efficient device for the lower part of bust vignettes consists in cutting out of thin card half-circular or V-shaped openings of various sizes and contours, which are faced with three layers of adhesive tissue, each layer projecting about $\frac{1}{8}$ in., more or less, from its neighbour, according to the size of the vignette and its distance from the negative. Fine strokes, close together, are added. Fig. 2 will make the device

Fig. 2.

plain, *a*, *b*, and *c* being respectively one thickness, and two and three thicknesses of the adhesive tissue. With a fair assortment, nearly every "head and shoulders" vignette can be fitted, and the beautiful way in which they will vignette off a dark coat must be seen to be believed. The lower part of the vignette proper, viz., for the head and shoulders, naturally receives no treatment.

The Dye Mixture.

The mixture recommended dries rapidly, and adheres well to waxed paper and especially so to adhesive tissue. Finely ground lamp-black as a pigment was first tried and found unsatisfactory, clogging and going ropy in use. Having some methyl violet dye at hand, this was substituted and has worked extremely well.

A little methylated spirit and ordinary spirit varnish are mixed approximately in the proportion of two parts of the spirit to one part of the varnish, and a few grains of the dye on the point of a knife are added and well stirred in. If on application to the tissue the mixture spreads, more varnish is required; if the colour be too pale, a few more grains of the dye are added. A very little experience will enable one to keep the compound in good condition, but occasionally it will be found advisable to allow the spirit to evaporate, when, with fresh additions of the three constituents, it will be in working order again. An ounce of the dye is sufficient for thousands of vignettes. If, perchance, any of the dye mixture gets on the clothes, place blotting paper on the other side, apply methylated spirit freely, and hope for the best. A No. 7 round red sable brush, as used for oil painting, is a convenient size, and with ordinary care will last for years.

Convenience in Working.

To avoid fouling the ferrule or handle of the brush, it is essential to keep the dye mixture in a jar with a wide mouth. Vaseline is sometimes supplied in small glass jars *without contracted neck*, fitted with aluminium screw-on covers, and these answer admirably. Some old rags and a second corked jar containing methylated spirit for cleaning the brush must also be at hand.

Fig. 3 shows in place a convenient arrangement, representing a cover of a half-plate negative acting as a tray, the jar, and

Fig. 3.

half of a half-plate negative (cut longways) to act as a palette. The brush is held in V-cuts. When charged with pigment, the hairs of the brush are allowed to rest on the bottom of the tray, to avoid any chance of fouling the V-cuts and indirectly transferring the dye to the fingers.

When a batch of negatives is being dealt with, it is a mistake to finish one vignette before the next is put in hand, as this will mean many unnecessary fox-trots between retouching desk and working bench, possibly of benefit to the corpulent, but involving waste of time. In practice the negatives are laid in a pile, are outlined as already described on cut sheets of tissue paper, which receive the numbers of the negatives. As dealt with, they are placed in another pile, which will correspond

with the order of the tissue papers. This is preserved during the subsequent operations, and a return to the retouching desk is only made when all the openings have been cut out and the adhesive tissue is attached.

Things to Avoid.

A consideration of the choice and lighting of backgrounds would demand an article in itself, but a few words on "undesirables" may be added.

For sketch portraits, naturally, the lighter and flatter the background the easier the vignetting and the better the effect. A crease in the background much in evidence in negative after negative may engender in the printer language which need never have been induced. "Cloudy" backgrounds are veritable brutes for vignetting, except when the corners only are covered and the lower-middle class nature of the thing is preserved. The plain background which normally prints the same decided tint as a flatly lit face often acquires, is a feature that never would be missed, for however soft the vignette may be, the general effect is a wash-out. A light background dropping on to a much darker floor covering is another combination not welcomed by the printer. Of a different nature, but extremely awkward from a vignetting aspect, are the included hands and arms of a proud mother in dark clothes supporting an astounded baby, set against a white background. Here a pair of white cotton gloves and overalls for the parent would often save the situation, or, at least, mitigate its severity.

E. A. S.

THE SCIENTIFIC AND TECHNICAL GROUP OF THE ROYAL PHOTOGRAPHIC SOCIETY.

The negotiations with the Council of the Royal Photographic Society regarding the establishment within the Society of a sub-body or group specially charged with the duty of encouraging and advancing the scientific and more technical branches of photography have at length been brought to a conclusion, and the "Scientific and Technical Group," as it is to be called, will very shortly be beginning its work as a kind of corporate body. The movement is one which most emphatically is deserving of all the support which those members of the Society interested in its special aims can give it, for, apart from its general aim of advancing in particular the more scientific and technical branches of photography, its constitution has been formed along lines which give to the Group a measure of self-management and permit of its members having a stake in its organisation and prosperity. A scheme of this kind is no doubt the best for the purpose, and, it is to be hoped, will achieve the results which the pioneers in the establishment of the Group have set before themselves.

The activities of the Group as at present defined may be broadly stated to be the provision of scientific or technical lectures or papers to be delivered at the meetings of the Society held on the second Tuesday in each month. Such meetings will, of course, be open to all members of the Society, whether members of the Group or not. The Group may also offer abstracts of papers, original communications, etc., for publication in the Society's "Journal," and may further prepare and print for circulation among its own members abstracts, translations, or communications which may be judged to be of too technical or special a character for the wider publication in the "Journal" of the Society. Such work as this latter, and also the administrative work of the Group itself, is to be paid for from the funds of the Group.

The subscription for membership of the Group has been fixed at 7s. 6d. per annum, which in the future will be due on January 1 of each year. Payment of this subscription now confers, however, membership of the Group until the end of 1920, and if made on or before to-day week (November 14) gives the entrant the right to nominate six members for election to the administrative committee of the Group. Up to the present 137 members of the Society have shown their interest in the movement by sending in their names, with expressions of their desire to participate in the work of the Group. Apparently it is the intention of the Group to issue a list of its members, and to indicate by a system of alphabetical marks

the subjects in which each member is particularly interested. The subjects thus singled out as representing the field of work of the Group are as follows:—Colour photography; cinematography; manufacture of photographic materials; photographic appliances (cameras, lenses, etc.); photo-mechanical processes; photo-micrography; pictorial and record photography; radiography; scientific applications of photography (astronomy, spectroscopy, etc.); sensitometry, and theory of photography.

It may be hoped that all those members of the R.P.S. who have the wish to further the advancement of these branches of photography will signify it by enrolling themselves as members of the Group, which they can do by sending the subscription for 1920 to Mr. F. F. Renwick, 35, Russell Square, London, W.C.1.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Getting Ready for Christmas.

I suppose that almost every studio photographer in the Kingdom is now looking forward to Christmas with somewhat mixed feelings, the extra cash coming in being somewhat discounted by the long hours of work. Now much time is wasted in many studios by using apparatus that is not in perfect order. Dark slides that require careful handling to prevent them falling open, cameras with loose backs, and many other little defects of a like nature, waste absolutely hours in some businesses. It may therefore be useful to look over some likely causes of trouble, and indicate how they may be met. This is a good time to set one's house in order, because although a defective piece of apparatus may work tolerably well when time is taken to humour its little whims, when it is used at a real rush job, such as most jobs will be in the coming season, it is apt to fail lamentably.

Let us take the camera first. Almost the most common fault is a loose back, caused by the locking nut failing to grip. This, of course, leads to out-of-focus negatives. Sometimes all that is required is a washer between the nut and the camera frame, but it is often necessary to renew either the nut or the pin on to which it screws. Any of the big makers will supply small fittings such as this. Any holes in the camera bellows should receive attention. If large, they may be covered with black court-plaster, but if only small pinholes they may be filled with a paste composed of powdered graphite in Secotine. This is also handy for filling in any holes in the woodwork. Cracked lens panels are not uncommon, but they should be replaced at once, or trouble is sure to ensue. If it is inconvenient to replace them, strips of wood should be stuck on the front of the panel across the crack, and the back should be covered with black velvet. This last is a good tip for all lens-boards, as it not only prevents any possible light-leakage, but also makes sticking of the lens-panel almost impossible. However, all cameras will not permit of the slight extra thickness.

Any missing screws should be replaced; sometimes they seem of very small importance, but their absence throws a great strain on those that remain. If the screw-hole has become enlarged it must be pegged with wood; match-sticks are often useful; they should be smeared with Secotine, forced well into the hole, and then cut off flush with the woodwork.

It is a risky thing to use an unsafe dark-slide at any time, but when doing rush work it is simply asking for trouble. A most annoying defect is the coming unhinged of the centre partition. This usually becomes slightly displaced, with the result that the slide either refuses to shut at all, or shuts incompletely; in the latter case fog is almost sure to result. Cloth hinges may be replaced by anyone of average dexterity, but metal hinges, unless it is just a case of lost screws, should be handed over to an expert. The catches holding the slides shut often become loose, with disastrous results. In the case of the L-shaped catch now generally fitted a tap with a hammer, to bend in the outer end of the L, will often do much good. Safety catches, to prevent slides being drawn except when required, often get out of order, but a screw-driver, a pair of pliers, and a little common-sense will usually bring them right again. Tripods are usually kept in pretty good repair, because

it is next to impossible to work at all with a faulty tripod; but sometimes the ferrule becomes loose, which results in slipping, and much annoyance.

I have left the shutter to the last of the camera parts. Sometimes a roller-blind, or studio shutter may be improved in its working by a clean of its working parts: a few slight adjustments are within the scope of the average "Pro," but serious damage is almost sure to result if anyone but an expert tackles the repair of a diaphragm shutter.

The lenses are unlikely to benefit by any attention, other than a good clean, which they should certainly have.

To depart from the actual operating gear. The enlarging lantern should be overhauled, and lamp-house and illuminant thoroughly well cleaned, but the most usual trouble with lanterns is a jerky, focussing movement. This is often caused by looseness of the clamping screws. A great improvement may often be effected by rubbing graphite from a "lead" pencil in all the places where wood slides over wood.

Any stray light from the lamp house or from the body of the enlarger should be cut out; it is a most frequent cause of fogged paper. The easel will probably repay a little attention; the clips, bars, or whatever it is that holds the paper, should be adjusted, and if the easel is one of the type that folds back for placing the paper it should be seen to that it comes up truly vertical, or else it will be impossible to get sharp focus all over the enlargement.

Printing boxes are usually kept in good order, because any defect is at once noticed, but it is as well to see that the arrangement for providing pressure on the paper is in order; also the felt pad should be renewed when becoming worn, or else unsharp prints, and even broken negatives may result.

In the dark-room the safe-light should be cleaned; broken dishes, or even cracked ones, should be replaced. And any taps that require washers must be attended to.

The dry-mounting press may be heating unevenly, which may result in the print sticking and the fissure failing to do so. This may be improved by a thorough clean out of the heating system, and, in the case of gas, by having the pipes blown through.

This note is not intended to be a complete list of all the ills that apparatus is heir to, but it may serve to point out a few of the most usual points to look to.

In conclusion, it is always as well to get in a small stock of "breakables," such as focussing screens, dishes, and bottles, before a rush. Then any accident is not so serious.—ARTHUR G. WILLIS.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications October 20 to 25:—

WATER FILTER.—No. 25,857. Photographers' water filter. J. E. Duggins.

ROLL-FILM ADAPTER.—No. 25,965. Roll-film spool adapter. J. F. Dukinfield.

PROJECTION APPARATUS.—No. 26,123. Optical projection apparatus. J. M. McAleary.

COPYING-ENLARGING APPARATUS.—No. 25,964. Apparatus for making photographic enlargements, reductions, and reproductions. E. Pascault.

CINEMATOGRAPHY.—No. 25,887. Shutters for cinematograph machines. W. Branson.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SENSITIVE UNITS FOR COLOUR PHOTOGRAPHY.—No. 128,781 (August 1, 1918). The invention consists in producing a coloured picture, in which are employed (1) a support consisting of a film coated on both sides with a light-sensitive film, and (2) a paper or other support coated with a sensitive film on one side. These films,

after treatment, are caused to form coloured component pictures, and are stuck together to form the composite three-colour photographs. The chief feature of the invention is that one of the supports before exposure is mounted in a frame, and remains therein until the various treatments and the assemblage of the two films have been effected. Further details of the process are given on another page in the "Colour Photography" Supplement. Jens Herman Christensen, Villa Sterrehus, Sövejen, Sölleröd, Holte, Denmark.

ROTATING PRINT WASHERS.—No. 132,978 (February 28, 1919). The invention is of apparatus for washing photographic prints, films and the like of the type having a perforated drum adapted to revolve in a tank holding water filled to a predetermined level in such a manner that the drum wherein the prints or films are placed is partially submerged or revolving in water when the apparatus is in use, means being provided for rotating the drum.

According to the invention a pipe disposed externally of the drum is perforated in such a manner that jets of water from the tube are directed at right angles through the surface of the drum to prevent the films from adhering to the inside of the drum, and also to assist in the complete agitation of the water.

Conveniently the drum may be driven by the usual water wheel, and the pipe, which may be submerged beneath the water, may be branched from the main supply pipe which feeds the water wheel in such a manner that water under the usual pressure from the main supply passes along the pipe and into the drum.

The drum is formed of perforated sheet metal, one section of

the circumference being adapted to form a lid a^1 for the insertion and removal of the prints; the drum is mounted to rotate on pivots a^2 in a water tank b , and is provided at the one end with a water wheel c , and to which a supply of water is directed for the purpose of rotating the drum.

In a position outside the drum and parallel to the axis of the drum a water supply pipe d is fixed, preferably in a position just below the level of the water e in the tank b , which water level is preferably above the pivot a^2 upon which the drum revolves, but below the upper part of the circumference of the drum. This supply pipe d is provided along its length with a series of perforations d^2 , which are adapted to form outlets from which jets of water d^2 emerge, the jets of water being adapted to take such a direction as to pass through the perforations in the drum into the interior, and thereby displace any of the prints which may have adhered to the interior surface of the perforated drum, and which jets of water d^2 are adapted to agitate the water in the drum in such a manner as to separate the prints in the drum. The perforated supply pipe d is preferably arranged on that side of the drum in which its circumference leaves the water e in the course of its rotation. J. and R. Oldfield, Limited, and Bernard Leslie Oldfield, both of Refulgent Works, Warwick Street, Bordesley, Birmingham.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—
E. P. G. DESIGN.—No. 391,449. Photographic paper. Eric Purselove Glover, 5, Park Lane, Leeds, Yorkshire; manufacturer and publisher of photographic specialties.
OSDA.—Nos. 392,325. All goods included in Class 39. The Houghton-

Butcher Manufacturing Co., Limited, Clifford Road, Walthamstow, London, E.17; manufacturers.
 O.S.D.A.—No. 392,326 All goods included in Class 8. The Houghton-Butcher Manufacturing Co., Limited, Clifford Road, Walthamstow, London, E.17; manufacturers.

New Apparatus, &c.

A Vertical Photo-Micrographic Camera. Made by C. Baker, 214, High Holborn, London, W.C.

A piece of apparatus for the microscopist who requires to carry out photo-micrographic work with the minimum degree of disturbance of his ordinary use of the microscope has been designed by Messrs. Baker in a most excellent manner. The photo-micrographic camera is held vertically, so that it is only necessary to bring the microscope underneath it, and to make a temporary light-tight junction of the two. For such a purpose as this rigidity is, of course, everything, and, therefore, it is well that we should say that it is impossible to speak too highly of the solid construction of the stand which supports the vertical camera. The

main upright is of solid steel, as is also the auxiliary swinging pillar to which the camera is attached. A pair of equally solid bearings allow of the camera being raised as a whole, and of its being drawn out to any required extension. Both these adjustments are instantly made rigid by the strong clamps which are provided. The camera has a maximum extension of 18 ins., and closes to within 4 ins. It is provided with a ground-glass focussing screen, with clear glass centre for critical focussing, one double dark-slide and self-contained shutter. In the quarter-plate size, the only one in which the outfit is at present obtainable, the price is £8 15s.

The Salex Enlarging Lantern. Sold by the C y Sale and Exchange, 81, Aldersgate Street, London, E.C.1.

This enlarging lantern embodies most completely the various features which of late years have come to be regarded as desirable, indeed almost essential, for convenience in the making of enlargements. These concern chiefly the negative stage which in the "Salex" is a detachable frame fitted with rotating turntable by which the negative image can be angled in any desired manner on the easel. This is done by rack and pinion adjustment, and the same convenient adjusting means are provided for up and down movement of the negative as well as for tilting the entire negative stage at an angle to the axis of the lens. The bellows connection between the condensers and the lamp-house is instantly removable, giving easy access to the condensers. The lamp-house itself is provided with rack and pinion adjustment, whilst the extension of the enlarger front is most ample, sufficient for the making of lantern slides from negatives by projecting them upon a reduced instead of upon an enlarged scale. The front itself is fitted with rising and falling panel, a feature which theoretically may be entirely wrong, yet in practice is found frequently to be of real service. The whole

apparatus impresses us as being very well designed and made. It is supplied in six sizes, for negatives $3\frac{1}{2} \times 2\frac{1}{2}$, quarter-plate, 5×4 ,

postcard, half-plate, and whole-plate. In quarter-plate size, with $5\frac{1}{2}$ -in. condenser, the price without lens is £11 10s., in half plate size, £17 2s., and in whole-plate, £30.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 4, Mr. A. H. Lisett in the chair.

A demonstration of the Raydex process of three-colour printing was given by Mr. F. R. Newens, who very successfully carried through the making of a three-colour print from the set of bromides taken from the customary colour-sensation negatives. The process is one abounding in details of manipulation, a feature of it which makes it difficult to devise anything spectacular in the way of a demonstration. Mr. Newens was therefore compelled to follow a somewhat humdrum course, and to explain to his audience the

operations involved in the process and the little niceties of manipulation which contribute to successful practice. If he said much by way of precaution, it was no doubt for the reason that he assumed entire unfamiliarity with the process on the part of his audience, by no means a bad rule to follow, but one, perhaps, which can be adopted by a demonstrator sometimes to an excessive degree. It must, however, be said that Mr. Newens provided the opportunity of members seeing for themselves the very simple and comparatively rapid operations which produce a three-colour print by the Raydex process. The lecturer uttered a plea for a greater degree of interest in the process by pictorial workers. He pointed out that the majority of the people who had taken up the process had done so chiefly out of a technical interest in its capabilities. Very few of them were artists, and, therefore, when he (the lecturer) looked at the monochrome work (on the walls of the lecture room) which formed the pictorial section of the Society's exhibition he felt convinced that there was a very great possibility in the process, if those whose aim and training was strictly artistic would test its capabilities.

On the conclusion of the demonstration questions were asked and answered, and on the proposition of the chairman the very hearty thanks of the meeting was accorded to Mr. Newens.

CROYDON CAMERA CLUB.

MR. F. C. REYNOLDS, forsaking for once his specialty "polarised light," gave an admirable exposition on "Colour," illustrated with many beautiful and ingenious experiments. With photography pure and simple the lecture had but little to do, though naturally connected with the art of the camera throughout. Some of the links might have been forged stronger, and doubtless in any repetition of a lecture worth many repetitions this will be effected. (Should this guileless observation put Richmond or Hammersmith on the track of Mr. Reynolds, he will kindly blame the triple-entente and not the reporter.)

When lecturing he has the happy knack of conveying the impression of being, so to speak, part and parcel of his audience—"just one of you chaps who has studied light and colour, you know," and happy to have an opportunity to chat about it. Yet, paradoxically, never does he assume his hearers know anything about the subject, and consequently he makes himself understood by all, including those whose intelligences have expanded in other, and often unknown, directions. Nevertheless, just one little trap he fell into when considering the "additive" and "subtractive" systems of colour reproduction, by attempting to explain the difference between them in more than few words and less than many words. The main idea embodied in each is clearly grasped, and was clearly described by him, but further elaboration leads to subtleties, not so easy to understand, and requiring full examination.

It would be highly inconvenient to attempt to allude to the many instructive experiments shown; even a deaf member would have been interested, and in addition would have understood a good deal. A very convincing experiment consisted in projecting on the lantern screen a brilliant continuous spectrum, and then passing along it discs painted with pure colours, which acquired different colours and depths down to blackness, as they progressed. Usually demonstrations on colour fixes the beginner with an idea that any subject including yellow, green, and red is outside the pale of an "ordinary" brand of plate. Mr. Reynolds supplied an efficient antidote for the misconception. "Suppose," said he, "we take a piece of glass coloured red throughout, which only permits the red of the spectrum to be transmitted, an ordinary plate will be practically blind to such rays. But if we take the glass, powder it to a pigment degree of fineness, and spread it on any surface, it can be photographed by the white light now reflected from its surface, along with the red, to which the plate is insensitive." And so with every red pigment known.

Mr. Reynolds' opinion of artists considered as experts in the theory of colour may be described as not being highly appreciative. Still, it may be hinted that many do know how to lay the stuff on and that a realisation of the theory of colour is no more necessary to them than is a knowledge of the ionisation of gases to bring a kettle to the boil on a gas-ring. Mr. Purkis, in the discussion, agreed that artists, as a rule, did not understand colour primaries. Much of the muddle was due to terminology. What an artist might

term "red" might be a "magenta." Similarly, if one asks a dyeman for "red," a "magenta" is usually supplied. If you want a "red," ask for "scarlet."

A most hearty vote of thanks was accorded Mr. Reynolds for an evening of exceptional interest, one which must have involved a large amount of preparation.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

VISIT TO GLASGOW.

At the invitation of the Glasgow Professional Photographers' Golf Club, the members of the Edinburgh Society spent a most enjoyable day at Glasgow on Friday, October 31. Some ten members left Edinburgh by the 10 a.m. train, and arriving at their destination an hour later, were met by the Glasgow men. The party then started by motor for Hillfoot Golf Course, situated some miles distant, and lying in a most beautiful part of the country. Even for the one or two who did not play, the walk round the course and the sight of the autumn landscape which was thereby afforded them were sufficient enjoyment in themselves. On arriving at the course the party were entertained to lunch in the club-house, and a photograph having been taken—upon what was a unique occasion in the annals of professional photography of the two cities—the players were arranged, and drove off. The weather was of the best, and the game was greatly enjoyed by all—in spite of the sad fact that Edinburgh was beaten by five games to three.

Afternoon tea having been served, the party now returned by train to the city. On arriving at the low-level station at Queen Street, and ascending the steep stair to the realms of light and air, the twenty stalwart golfers, labouring under the weight of clubs and the day's achievement, were obliged to pass between two swarthy ticket-collectors. It was considerably to the mortification of the party, therefore, when one keeper of the gate was heard to observe to his fellow, over the heads of his victims, "There'll be nae gress left on Hillfoot Golf Course the day, Charlie!"

The Edinburgh men were now entertained to dinner, where they were joined by others of both cities who had not participated in the game. A letter of apology for absence had been received from Councillor Drummond Shiels, of Edinburgh.

Mr. Drummond Young, president of the Edinburgh Society, was formally introduced by the captain of the Glasgow Golf Club, Mr. Weir. It had been at the back of their minds, said Mr. Weir, that the formation of the golf club among Glasgow photographers has been merely a preliminary step toward the forming of a professional society in that city, and that in this connection Mr. Young would speak upon the experiences of the Edinburgh Society. Mr. Young then gave a brief account of the work done by the society since its inception, explaining its aims and objects, and advocating strongly the inauguration of a society upon similar lines in Glasgow. The value of an association to any kind of business man was pointed out, and it was suggested that the societies of both cities could afterwards amalgamate to form the nucleus of a Scottish Society of Professional Photographers. Several questions were then asked and suggestions made, and it was generally felt that such an association should immediately be formed in Glasgow.

Mr. Young then proposed the health of the Glasgow men, and thanked them heartily on behalf of himself and his fellow-members for the delightful day and the lavish hospitality which had been given them, and he extended to his hosts an invitation to come through to Edinburgh in the spring when, it was hoped, the men of Edinburgh would be able to reverse both the kindness and the score. The toast of the guests then followed, and Mr. Young, in replying, proposed the health of Mr. Robt. Scott, of Kodak, Ltd., who had been chiefly instrumental in organising the Glasgow Golf Club, and to whose credit, along with that of Mr. Robertson, the success of the day had been due. Mr. Scott thanked the meeting in an eloquent and thoughtful speech.

The Edinburgh party returned by the 9 p.m. train.

MR. ROBERT H. RICE, whose complaint of alleged profiteering figured in the report of the Professional Photographers' Association published last week, asks us to correct the name of the district given as that of his place of business; this should have been Waltham Cross, not Walthamstow.

Commercial & Legal Intelligence.

AT THE LONDON BANKRUPTCY COURT on Friday last the first meeting of creditors was appointed to be held under the failure re Richard Cardwell Barron, of 7, Queen Street, Bloomsbury, W.C., photographer, lately carrying on business at 19, Cheapside, E.C., and lately residing at Shedfield, Ashley Road, Thames Ditton.

The Receiving Order was made on the petition of a creditor, the act of bankruptcy being the debtor's failure to comply with the requirements of a bankruptcy notice. The debtor had not surrendered under the proceedings, therefore no information was available as to his liabilities and assets. An officer of the Court had attended at the debtor's various addresses, and found that he had not been seen at any of them for some time. The debtor's wife had been found, but she stated that she had been separated from the debtor for 8 or 9 years, and during that period he had not contributed towards her support. There was no property at her address belonging to the debtor, and she knew nothing about his affairs. The Official Receiver went to Shedfield, Ashley Road, Thames Ditton, and was told that the debtor left there about three months ago. It was stated that at Thames Ditton he went in the name of Barron, Sandey, and Smith. The debtor formerly rented the house at £45 per annum in the name of Sandey, but he left in June last owing a quarter's rent, and the landlord was making a claim against him for dilapidations. As there was not a quorum of creditors present no resolutions could be passed, and the estate was formally left in the hands of the Official Receiver.

LEGAL NOTICES.—A first dividend of 5s. in the £ has been declared in the estate of Henry Arthur Yvery Heathcote, photographer, of, and lately carrying on business at, 22, St. James' Street, Piccadilly, London. The dividend was payable on November 6, 1919, at the offices of the Trustee, 1, Guildhall Chambers, Basinghall Street, E.C.

A first and final dividend at 11s. 7½d. in the £ has been declared to the case of Charles Frederick Siedle (trading under the style of Siedle Bros.), 60, Walter Road, Swansea, and 13, Heathfield Street, Swansea, photographer. The dividend was payable on November 6 at the Government Buildings, St. Mary's Street, Swansea.

News and Notes.

THE UJAH OINTMENT COMPANY, of London Street, Oxford, has just issued a six page circular of testimonials from those who have benefited by the use of the Ujah preparations in the treatment of developer skin poisoning. A copy of the leaflet is obtainable free on application.

EDINBURGH-GLASGOW GOLF MATCH.—As reported on another page, professional photographers of Edinburgh and Glasgow, on the occasion of a joint meeting held at Glasgow on Friday last, October 31, took part in a very enjoyable golf match on the Hill-

[Photograph by Romney, Glasgow]

LEFT TO RIGHT: STANDING.—Messrs. J. W. Romney, (Glas.), Thomson (Edin.), McFall (Edin.), Whyte (Glas.), Mitchell (Glas.), Drummond Young (Edin.), Scott (Edin.), Polmont (Helensburgh), Macalpine (Edin.), Scott (Glas.), Ross (Edin.), Rushbrook (Edin.), Helms (Edin.), Black (Glas.), Phillips (Edin.), Dewar (Glas.).
SITTING.—Messrs. Wells (Glas.), Yerbury (Glas.), Whyte (Glas.), Robertson (Glas.), Seagill (Glas.), Romney (Glas.).

foot course, the use of which was kindly granted by the Douglas Park Club. We are indebted to the firm of Mr. George Romney, of Sanchiehall Street, for the photograph of the party on the golf course.

PACKARD SHUTTERS.—Messrs. J. H. Dallmeyer, Ltd., of Church End Works, Willesden, N.W.10, advise us that they have been appointed sole agents for the United Kingdom for the celebrated "Packard-Ideal Silent Studio Shutters," and that a very large consignment has just arrived, enabling them to supply any of the various sizes listed from stock.

AERIAL PHOTOGRAPHY.—In the House of Commons during the week-end Lieut.-Colonel Moore-Brabazon asked the Under-Secretary of State to the Air Ministry what steps, if any, have been taken to use the experience obtained during the war in aerial photography for mapping purposes towards revising and helping in ordnance survey work in England, in view of the fact that so many maps are now out of date?

Major-General Seely: As my hon. and gallant friend is aware, the Board of Agriculture is responsible for Ordnance Survey Maps. A Committee, with representatives of the War Office, Admiralty, and Air Ministry, have been considering the general question of maps, including those specially required for air purposes, for which, undoubtedly, aerial photography will be of the greatest value.

Correspondence.

THE ETERNAL QUESTION.

To the Editors.

Gentlemen.—Regarding the letter from "Still Hoping" in the issue of 31st ult., may I suggest that a great improvement in conditions would undoubtedly be effected if assistants would join the National Union of Shop Assistants?

Efforts to form a "Photographic Assistants' Union" are apparently hopeless; the proposal to form a Union under the auspices of the P.P.A. will appeal to very few assistants.

Possibly the Union of Shop Assistants would lend their organisation for the formation of a photographic section.—Yours faithfully,

A. W. WOODMANSEF.

185, Crown Street, Peterborough, November 3.

BARIUM SULPHIDE AND SULPHIDE TONING.—A WARNING.

To the Editors.

Gentlemen.—Owing to its better keeping qualities and greater convenience in handling, the substance being a dry powder which appears to be non-hygroscopic, the use of barium sulphide in sulphide toning is increasing amongst amateurs. I should, however, like to point out that, unless the prints are very well washed before putting in the barium solution, and also between the barium solution, and any clearing bath which may be used, there will be formed in the emulsion insoluble salts of barium, which in the case of glossy papers may utterly ruin the surface of the print. Amongst these insoluble compounds I may mention the sulphate, phosphate, chromate (yellow), and ferricyanide. Needless to say the corresponding sodium salts are soluble, so that no trouble of this kind arises when sodium sulphide is used.

Should, however, it be desired to continue the use of the barium compound, the remedy is quite simple. Before using the barium solution add to it a little solution of Glauber's salt. This, if sufficient be added, precipitates the whole of the barium as sulphate, in which form it is quite innocuous, whilst the sulphide remains in solution in combination with the sodium of the Glauber's salt. It is not necessary to filter, as the barium sulphate quickly settles. The cost of the Glauber's salt is a few pence per pound. Of course, this is exactly equivalent to using sodium sulphide in the first instance.—Yours faithfully,

T. H. GREENALL.

Chorley, November 4, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- W. P. S.—According to the latest edition of Kelly's Directory there are 12 there.
- J. E.—We do not think that you will gain anything by the arrangement you sketch. You would do better, we think, to add two more lamps to your existing installation.
- W. N.—Sketch portraits are not made by bleaching, but by vignetting and blocking out. You will find full working instructions on their making in the little manual, "Sketch Portraiture," which our publishers issue, price 10d. post free.
- R. K.—Most of the exhibitors at the exhibition of the Royal Photographic Society are open to supply duplicates of their exhibits. The prices in many cases are stated in the catalogue. In others, no doubt they are obtainable direct from the exhibitors, addresses of whom you will find in the catalogue.
- D. K.—We think under the New Retail Businesses (Licensing) Order the addition of dealing in apparatus and materials to your present business would be regarded as the establishment of a new retail business, and in that case you require to obtain a licence for the addition. The office for your district is 15, Athol Crescent, Edinburgh.
- J. W.—1. Canvassing for enlargements is certainly a business within the Retail Businesses (Licensing) Order. Any licence would apply only to one particular town. 2. You would have to obtain a licence to take ferrotype portraits, and in this case also a different licence would have to be obtained according to where the work is done.
- H. G.—If the half-tone block is at all a decent one you ought to get a very much better print from it than the specimen sent, which is a very poor thing. We think your best plan would be to send the block to a photo-engraver, and get him to make the best etcher's proof from it. It is quite impossible to make a copy from the block itself.
- J. B.—1. You certainly require a licence, the office for which is 99, Queen's Gate, South Kensington, S.W.7. 2. Generally speaking, such functions require to be taken in at least 12 x 10 size, and the best camera, for the sake of lightness of weight, is one of the somewhat tapering-bellows type such as the Watson "Acme." The lens should be one of about 16-in. focal length.
- S. AND H.—As, apparently, you are aware, no licence is required for amateur developing and printing business which is obtained through the post or through the medium of advertisements in newspapers which circulate throughout the country. But if a regular photographic business of any kind is started a licence is required. The office for your district is 80, Westbourne Terrace, Paddington.
- C. L.—The Retail Businesses (Licensing) Order applies to any kind of photographic business carried on regularly—that is, with people in the neighbourhood. It would certainly apply to you, and the office to which you should apply is Harehill Barracks, Leeds. In some towns the authorities also insist that a house-to-house canvasser for portraits should have a hawker's licence. You can only ascertain this by making application to your local head police office.
- C. A. C.—The fixing bath formula in the "B.J." which is made up with metabisulphite is just as good for gaslight papers as the acid hardening fixing bath containing also alum. Both of these baths may be used for both plates and papers without any harm,

so long as they remain free from stain, but it is a mistake to use baths for prints which have been much used for plates since it is difficult to tell from the appearance of the print whether it has been fixed thoroughly or not. There is no special necessity to varnish negatives which have been intensified by the chromium method. Such negatives are quite as permanent as those unintensified.

- G. K.—The only two systems of gas lighting for studio work are the "Howellite," of Messrs. J. J. Griffin and Sons, Ltd., Kemble Street, Kingsway, W.C., and the "Powerful," of Messrs. Kodak, Ltd., Kingsway, W.C. Both of these installations will certainly give decent results, but exposures are relatively long, five or six seconds under good conditions of lens and plate, and the heat of the burners (there are about 20 of them) makes the installation unsuitable for use in summer in a studio of small size or in any room which is not very well ventilated. The cost of the installation is, or was, about £5.
- A. N.—The number of lamps or total candle-power depends upon the shortness of the exposure required; for very rapid work 6,000 c.p. is needed, but in the ordinary way 3,000 c.p. (say six 500 c.p. lamps) will be sufficient. If these are placed in a curve so that the first is opposite the middle of the background about 8 ft. away and 8 ft. from the floor with the others rather lower until the end one is near one side of the studio and about 6 ft. high, you will have a good general arrangement. The box arrangement would be rather too concentrated. The best way of fixing is to have the counterbalanced reflectors as sold by the General Electric Company, 67, Queen Victoria Street, London, E.C.
- A. F.—1. The office for your district is 99, Queen's Gate, South Kensington, S.W.7. 2. It is doubtful whether the taking of photographs for the newspapers is a retail business according to the Order, but certainly a licence for ordinary portraiture would also cover the making of photographs for the newspapers. 3. You do not tell us the working space so we cannot tell whether we are recommending a lens of too long focus, but your requirements will be best met by a carte-de-visite portrait lens of 6 or 7 in. focal length. This will give you very fine definition on a quarter of a $\frac{1}{4}$ -plate, as good as any you can get with a much more expensive anastigmat, and the lens will be more rapid than any of these latter. If you want a shorter focus than 6 ins., the best choice you can make is one of the high-class $f/4.5$ anastigmats, such as the Cooke or Ross "Npres."

TRADE MARKS IN CHINA. By W. B. Kennell.....	664	ANSWERS TO CORRESPONDENTS....	672

SUMMARY.

Advertisements which are "definitively" received by noon to-morrow (Saturday) may still be in time for inclusion in the forthcoming "B.J. Almanac."

The complex questions concerned in the preservation of rights in trade-marks in China was recently the subject of an exhaustive paper read before the Shanghai Advertising Club by Mr. W. B. Kennell, who dealt at length with the various methods open to European firms in protecting themselves against infringement of their trade-marks by other Europeans and by Chinese and Japanese merchants or manufacturers. (P. 664.)

In a contributed article Mr. Ernest A. Dench writes in an optimistic spirit of the business which may accrue to the photographers taking up the use of the cinematograph camera. (P. 661.)

In his article this week "Practicians" deals with some of the questions which arise in making a change from one studio to another. These concern not only the lighting conditions, but also business and social matters which have their influence upon the maintenance of the previous patronage of the studio which is taken over. (P. 659.)

A writer in "American Photography" on the making of photographs for commercial purposes emphasises a caution as to the mistake of quoting low prices in the idea that they will appeal simply on account of their lowness. (P. 662.)

The death has occurred of one of the old professional photographers, Mr. J. T. Chaffin, of Yeovil. (P. 663.)

A case of some interest in connection with the prices of mounts was heard on Tuesday last in Shoreditch County Court, when judgment was given on the price question and also on the point as to whether goods retained for a considerable period by a customer had or had not been ordered. (P. 669.)

The dinner of the Croydon Camera Club last week was a happy re-creation of a function which in pre-war days was among the most enjoyable of the photographic year. (P. 668.)

In outdoor photographic work in winter some very ordinary yet important precautions need to be taken as regards the care of outfit, choice of plates, and avoidance of moisture. (P. 658.)

Particularly for work in winter there is an advantage in making up developing solutions of quadruple the normal strength so as to allow of the working developer being compounded, when necessary, with a larger proportion of pyro. (P. 657.)

A further means of obtaining prints of decent contrast from negatives taken under dull lighting conditions is mentioned on page 658.

One or two minor items which contribute to the satisfactory use of festoon blinds in the studio are the subject of a paragraph on page 667.

EX CATHEDRA.

To-morrow Only. Although we announced last week that to-day, Friday, is the latest time at which advertisements may be accepted for the forthcoming "British Journal Almanac," we learn from our publishers that it will probably be possible for them to include in the volume announcements the order for which is definitely given before noon to-morrow, Saturday, November 15. In the case of these eleventh-hour orders, it is understood that the "copy" for the advertisement follows immediately. Time presses; a large part of the "Almanac" is now in the printers' hands, and the prompt setting and proofing of the advertisement section are necessities for the carrying out of the scheduled programme of printing and binding, details of which, in the case of a large book like the "Almanac," have to be settled long in advance.

* * *

Strong Developers. Although most plate-makers publish formulæ for making pyro-soda developers in quantities of 80 ounces of each solution, this is not always the best way of mixing the developer. It permits of dilution, but does not provide for increasing the strength should occasion arise, nor does it allow the proportions of soda and pyro to be varied in a convenient manner. For example, it is impossible even to double the amount of pyro in the mixed developer, as there is only the required quantity in the pyro solution before any soda is added. In the winter it is often desirable to use a more concentrated developer to obtain density from rather flat subjects, especially copies. This is quite easy if the solutions are made up to 20 ounces only in bulk, the same quantity of chemicals being used as for the 80 ounces of the original formula. There need be no confusion in diluting to normal strength, as it is only necessary to take as many drachms of each solution as ounces of developer are required, and to make up to the full bulk with water. If double the pyro only or double the soda be required, the extra quantity of concentrated solution is added, and then diluted to make the same bulk. In cases where the solutions are not used in a day or two the stronger solution will be found to have much better keeping qualities.

* * *

Festoon Blinds. There are one or two little details in connection with the fitting of festoon blinds which it is as well to bear in mind. One is that the wires used should be as smooth as possible; a good tinned or galvanised single iron wire is better than a twisted or plaited cable. Another is that the wire should not be too thick, as a thick wire needs a very strong pull to keep it taut. The rings on the curtains should be large enough to pass over the straining bolt, so that it is not necessary to

take the latter off the wire every time the curtains have to be washed or cleaned. During the winter the white curtains should be frequently washed, and this is easily done if they can readily be dismounted. It is an excellent plan to have two sets, so that a clean set can replace the soiled ones at once. There is then no occasion to hasten the laundry folk, and if the washing be done at home there is no need to remove the rings if these are solid brass. If electro brass or tinned iron rings are used there is a great risk of iron-mould stains, which cannot occur with brass rings. For the dark blinds, black or other dark-coloured Bolton sheeting, as was used for Zeppelin blinds, will be found a very satisfactory material: not only is the fabric thicker, but there seems to be much less tendency for the colours to fade.

Greater Contrast from Winter Negatives

Owing to the softer lighting prevalent during the winter it is often difficult to obtain a sufficiently brilliant result in the finished print. Many photographers' showcases can give abundant evidence of this in the case of football or other groups, taken perhaps late in the day. The negatives give prints lacking in contrast and in the brilliance beloved of the non-photographic public. Under these conditions it is a good plan to increase the contrast of the picture by the following simple means. The negative is slightly under-developed, yielding an image on the weak side. The prints are made upon one of the vigorous grades of gaslight paper, the idea of slightly under-developing the negative being to produce a negative more suited to the paper and preventing the harshness that would result if the negative were of full density. It is surprising what a great deal of increased contrast may be obtained in this way, and the plan is commended to all photographers engaged in out-of-door work during the winter season.

Time Saving.

In many businesses a great saving of time, not to say an avoidance of error, might be made by giving distinctive letters and numbers to the various articles and styles dealt with instead of giving a more or less detailed description in words. During the war we have got accustomed to this method in connection with Government forms, and we realise how much time is saved by asking for Army Form 6142 instead of giving details of the application or report which it is desired to make. This principle is particularly suitable for the photographic industry, where a multiplicity of sizes, colours, surfaces, and mounts have to be dealt with. One large trade firm has already done this, and has issued samples bearing distinguishing letters and numbers, so that if a customer requires a glossy print sepia-toned with white margin he has only to give the size and a certain number, say A.2, to ensure accuracy in the execution of his order. Some of the enlarging firms have tried to do something in this way by giving fancy names to the styles, but this is clumsy, and more likely to lead to mistakes, besides not allowing for slight variations in style to be readily classified. In large portrait businesses each current style might be numbered on the same system, saving space in booking and preventing misunderstanding in the work rooms.

The Choice of a Camera.

We are sometimes asked by beginners in portraiture to advise them in the selection of their studio outfit, without any indication as to the class of work they propose to do, as if there was a standard camera which would be suitable for any studio in any locality. This is, of course, very far from being the case, as the apparatus which is suitable for a high-class business is not likely to be the best, irrespective of cost, for a cheap one. The orthodox

12 x 10 studio or salon camera with a repeating-back attachment for cabinets is undoubtedly the best one to choose for the first, while the second must be fitted with such an apparatus as will allow a large quantity of work to be done with the smallest expenditure of material and labour. If small "panels," passport portraits and post-cards form the bulk of the work, one of the special cameras made to give a number of exposures upon one plate will be found most useful, this being supplemented by a camera, say of whole-plate size, which could be used for cabinet portraits and groups as well as general outdoor work. In order that portrait lenses could be used this camera should be of the parallel bellows form, and should be provided with a studio stand as well as the usual tripod.

OUTDOOR WORK IN WINTER.

WHILE the amateur worker can pick and choose the opportunities for satisfactory work during the winter months, his professional brother has to take things as they come, and to obtain the best results which are possible in the case of groups, estate subjects, or other outdoor commercial work with which he may be commissioned. Therefore, he is under the necessity of adjusting his practice to the very different conditions of the season, on which subject some few notes may be not without interest. If some of the points upon which emphasis is laid seem to be obvious, it may be urged in extenuation of their mention that cases frequently come to our notice where their neglect is the cause of work of indifferent quality.

In the first place, something requires to be said on the greater degree of protection which apparatus requires during the damp winter months than is often given to it. A stout case, waterproof and damp-proof, may be set down as an absolute necessity. For such a case there is no more suitable material than leather, but if the present considerable cost of a leather case is an objection, a very efficient substitute may be found in a box made of the light three-ply wood and covered with waterproof canvas or twill. A case of this description will give not the slightest ground for complaint as regards its satisfactory protection of the apparatus, if the precaution be taken to keep the camera and slides well wrapped within it in a waterproof focussing cloth. This latter may be regarded as an essential in outdoor winter photography in any circumstances where the care of an expensive camera is a consideration. Apropos of this matter, it is worth while to remind the photographer that an outfit which has been used throughout a day of damp weather should be given rather more than ordinary care on the return to the studio. It is worth while to take the trouble to open out the camera and wipe it thoroughly with a dry cloth, for there is certain to be a film of moisture over the instrument, no matter how waterproof the case may be. It is just as well to leave the camera fully extended in a warm, dry room for a few hours, and attention to these points will be found to be the secret of keeping the apparatus in first-class condition and of avoiding the warping of its more delicate woodwork.

In the matter of plates a common mistake is that of using the fastest plates which can be got. For all stand-camera work the photographer is immensely better equipped with a fairly slow plate with which contrast can readily be obtained, and which, moreover, is one that may be forced in a slightly warm developer in order to bring out shadow detail. Unless a special subject calls for a plate of the orthochromatic or panchromatic variety, the outdoor worker is best equipped for the difficulties peculiar to the winter season when his dark-slides are loaded with plates of "ordinary" rapidity, that is to say, of a marked speed of about 100 H and D. In conjunction with a fairly con-

concentrated developer it is remarkable what superior results may be obtained under dull weather conditions in comparison with those made on plates of the ultra-rapid kind. For hand-camera work a faster plate is, of course, a necessity, but here again there is a positive advantage in using one which is several degrees short of the most rapid obtainable, and thus facilitates the making of negatives of decent contrast under unfavourable conditions. The softer lighting of winter, while it imposes the necessity of lengthening hand-camera exposures where possible, is undoubtedly best compensated for by the use of a plate which is generally classed simply as "extra-rapid."

A further matter for caution, in avoiding flat results, is the freedom of the surfaces of the lens from condensed moisture. Photographers are generally familiar with the deposition of moisture when a lens is taken from a cold atmosphere into one which is both warm and charged with moisture. But in continuous outdoor work in winter dimming of the lens surfaces readily occurs in a variety of circumstances, and is one of those things which is apt to escape observation. A final polish of the glass elements is one of those things which ought not to be neglected, on which account the type of lens consisting only of two cemented combinations is on this score preferable to that in which a number of single elements make up the objective. It is a matter of a few seconds to polish the surfaces of the former, whereas in the case of the latter the removal of the glasses by chilled fingers is a thing to be avoided. A preparation, "Clarocit," is now obtainable from Fallowfield's and other large dealers, the application of a thin film of which to the lens surfaces will go a long way towards

obviating a deposit of moisture which can have any injurious effect.

A further point to which reference may well be made is that of developing plates as soon as possible after exposure, or at any rate keeping them in a dry condition until development. Gelatine is a material which absorbs moisture readily, and though exposed plates in a dry condition retain the latent image in an unimpaired condition for a very long time, it is, we think, not safe to assume that the same holds good when the plate is damp. Although we cannot recall any scientific measurements in support of the belief, we think the keeping of plates in a damp state for some days between exposure and development is a cause of flatness and weakness in the negative.

The photographer himself must not be neglected in these winter provisions. The outdoor worker who may have to spend a day on damp ground should look to his own comfort in the way of footwear. Stout boots should be worn, and may well be further brought into waterproof condition by plentiful application of a preparation such as dubbin. Many, too, will find a pair of leggings or puttees a positive comfort in keeping the whole body comfortably warm. No photographer can expect to do work to his full satisfaction when hands and feet are cold. Although gloves are felt to be awkward by many in handling focussing gear or other parts of the apparatus, yet if it is possible a pair of stout woollen gloves (better than leather on account of their flexibility) should be worn as much as possible, or if they are objected to a pair of knitted mittens, which leave the fingers free and unrestricted, are not to be despised in very cold weather.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).

Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).
 Miniatures (Sept. 19).
 Printing Portrait Negatives (Sept. 26).
 Wedding Groups (Oct. 3).
 Combination Printing (Oct. 10).
 Flashlight Work (Oct. 17).
 Flashlight Portraiture (Oct. 24).
 The Question of Outfit (Oct. 31).
 Telephoto Lenses for Professional Work (Nov. 7).

CHANGING QUARTERS.

There are few photographers who work throughout their career in the same studio. It may be that a change is necessitated by municipal improvements, the expiration of a lease, or by the opportunity arising of securing more desirable premises.

In most cases it will be found that the new quarters require a little "getting used to," and the ease with which this is done largely depends upon the knowledge of essentials possessed by the photographer. Many of us recollect a *cause*

celebre of a few years ago, when a Society artist who moved into a new studio in the same street as the old one, but with a different aspect, brought an action for damages against the firm who had designed it on the grounds that it was impossible to produce a certain distinctive class of work there. Many expert witnesses were called on either side, but the weight of evidence was overwhelmingly in favour of the new premises, so that in addition to the temporary loss of prestige, the photographer had to face a heavy bill of costs. Here the whole thing in a nutshell was that the particular style of lighting was one which came easily in the old premises, but the photographer imagined it to be due alone to his own skill and taste, and, failing to reproduce it, blamed the new studio. Such extreme cases rarely occur, but in a lesser degree the trouble is fairly common, especially with those who have not had the advantage of working as assistants in various studios before starting on their own account. Nowadays studios are not planned with the uniformity that formerly prevailed, when only a few daring spirits would venture upon any place which had not a full northern aspect, so that we must be prepared to make the best of any point of the compass, and with a little intelligent consideration this is not so difficult as it might appear.

If possible, it is a good plan for the newcomer to study the work of his predecessor, so as to ascertain what class of lighting had actually been produced. This will often give encouragement, and in all cases will be instructive. As an instance I may mention a studio with a top light only in which most excellent work had been done, but which the newcomer quite failed to equal. I was invited to visit it, and found that an alteration had been made which had destroyed all chance of good lighting. The studio was originally very wide, so that by placing the sitter well to one side the light fell obliquely upon the figure and obviated the top light effect. My friend had decided that the studio was unnecessarily wide, and had cut off nearly one-half to form dressing-rooms and a negative store, with the result that he was left with a comparatively narrow top light which practically defied control. In another case the new tenant did not care for his predecessor's work, and sought to improve upon it. This was easily done by removing some boarding which had been placed over the most useful part of the roof.

The man who moves into a north-light studio will usually find all plain sailing, but if he moves from such a studio to one where the sun is upon the glass for the greater part of the day, considerable modifications of his procedure will be necessary. Here clean thin white blinds or curtains must be used to cover what would be clear glass in his old studio, and it will probably also be advantageous to be able to change working ends at different times of the day.

Difference in height of the studio will sometimes cause a little difficulty in obtaining certain effects of lighting. In a low-roofed studio a slight change of the blinds causes a much more decided effect than it would in a high-roofed one; in the latter case portable head or side screens may be needed to produce the desired result. The nature of the glazing is also an important factor. Ground glass gives a uniformly soft effect, and is more in place in a southern or western aspect than in a northern one, where it will tend to produce flatness. It is often very beneficial to replace three or four breadths of ground glass by clear, which will give more sparkle in dull weather. Rolled or ribbed glass is much better than ground, as it diffuses the light without intercepting any, and does not give so much glare if the sun strikes upon it. Little difference in working will be noticed as compared with clear glass, while of course it prevents overlooking as effectively as ground glass.

The photographer who takes over a studio should not accept matters as they stand, but endeavour to make the working conditions as nearly like those to which he has been accustomed as possible. As a rule, a good clean-up of glass and blinds is necessary, and the sooner this is done the better. A general renovation of studio, reception and dressing rooms is calculated to make a good impression upon both old and new customers, who are not slow to notice these things, though they may say nothing at the time.

When taking over a going concern, the nature of the former proprietor's *clientèle* must be carefully studied and the greatest care taken to avoid offending them. In West-end studios the type does not vary much, but in provincial towns and in many suburbs the connection may be mainly among members of a certain denomination, and a change of proprietorship such as I have known, from an Anglican sidesman to a sporting freethinker, is likely to cause a large number of secessions, whose places have to be filled by a new class who consider only the pictures and not the producer. For the same reason it is not wise to sweep away all the old styles until it is certain that customers prefer the new ones, although it is very desirable to educate sitters into an appreciation of better-class work. We are all naturally more or less critical, except concerning our own business and our own productions. In taking over a studio we should be critical of the work and the style of business as it stands. In some respects we may find that the old proprietor knew more than we do, and in such cases his example should be followed, and any improvements which suggest themselves added. For example, if he was dilatory in sending out proofs and finished work, a special effort should be made to expedite delivery. If he was inclined to be disagreeable over re-sittings, we must be more obliging. These, of course, are the commonplaces of retail business methods, but photographers are not always alive to them. As far as the staff is concerned, I am rather inclined to advise following the example of the clergy and the licensed victuallers. In both these "industries" it is usual for the incomer to bring a new staff with him—curates or barmaids, as the case may be. There is nothing which hampers a business man so badly as to have a staff which thinks it knows how to run his business better than he does, and it is best to get the matter over before taking possession.

In the case of taking over a business as it stands, a careful inventory of the articles included in the sale should be demanded before any money is paid. I mention this because of a case which once came under my notice where many articles of furniture and some apparatus was removed by the original proprietor on the plea that they were not his own property, but lent by a relative. In such circumstances the purchaser has either to grin and bear the loss or to resort to legal proceedings, while if the ownership had been clearly defined before any payment was made, a deduction could have been claimed if deemed equitable.

A word of advice to assistants. I have pointed out the advantage the assistant who becomes a proprietor possesses over the ex-amateur who buys a business without studio experience, but it rests with the assistant to make use of his opportunities. He should not be content with merely making such sittings as may come his way, by using his employer's "stock lighting," but should endeavour to find out the capabilities of the studio for himself. Years ago there was often great jealousy between employers and their helpers, but I am glad to say that this is in a fair way to disappear, and most photographers are now willing to help their assistants to improve their work. In more than one case this attitude proved to be the salvation of the business when the employer was called up for active service.

MAKING MONEY WITH A MOTION-PICTURE CAMERA.

THE ambitious young man or woman determined to break into the studios as a motion-picture photographer will find his or her progress barred by the fact that the number of staff camera operators is necessarily limited. The ranks are already overcrowded, and unless you have a whole string of successes to your credit, your only chance of attaining your ambition lies in working your way through the film factory.

But there is nothing like the school of experience as a means of ultimately becoming skilled in this particular kind of work—work that is as exacting as it is fascinating. You don't need to possess unlimited capital to enter the field as a free-lance, though, of course, the more money you have at your command the more you can accomplish.

The free-lance cinematographer, no matter whether he resides in a small town or a large city, need not complain of the lack of opportunities which lie at his very door. I will dwell briefly upon the principal ways of turning the motion-picture camera to profitable account.

The latest development is film-motion portraiture. Were you to be "registered" before the exacting lens of the motion-picture camera for eight minutes, no less than 7,680 separate portraits would be taken at the rate of sixteen a second. Each portrait would be a momentary record of the sitter's face, and not one facial expression would be lost. On the screen you would be under the eye of the spectator for eight minutes. Each of the 7,680 photographs would not be a good likeness, but it would be the whole number projected in rapid succession that would give the faithful picture.

You can retouch and fake a photograph to suit, but you cannot tamper with a film. In fact, the only way is to do the faking beforehand by making up, and this does not always convince.

Who would not like to have a permanent record of all the quaint expressions that make a baby so adorable? They are lost to us as he grows older, but if he were to pose on every birthday we would be able to follow every stage of his childhood, and present the precious strip of celluloid as an appropriate coming-of-age gift. S. H. Lifshay, a Brooklyn, New York, photographer, makes a speciality of filming children in action, and brings out their pleasing characteristics. He also shows them at play with their pets and their favourite pastimes. Children are born photo-play actors, consequently they require comparatively little coaching.

A wedding occurs once, and it was left to a Frenchman to advertise something better than a group photograph. "Nuptial Cinema.—To Engaged Persons," runs the advertisement. "Do you wish to preserve a vivid, living recollection of the happiest day of your life? Have a film photographed of the ceremony (civil or religious) of your wedding, and in after years you will be able to see yourselves on the screen—young, loving, full of hope for the future."

One couple I know who married in 1909 permit their wedding movie to repose in the bank, only taking it out on each anniversary for their benefit and that of loving friends.

Other occasions on which motion-picture films might be taken are birthdays, vacations, and other family gatherings. By making a practice of recording such events, we should find many faults in ourselves which we did not believe before existed. We would also be able to correct these manners in deportment, speech and dress, and improve ourselves socially as well as in a business way.

Go to the local manufacturing factory and offer, for a fair consideration, to record on celluloid the manufacturing side of

the products, the size of the plant, how admirably situated it is, and how the welfare of the employees is studied. You can, perhaps, weave a little story around the whole. Suppose the article is machinery of some kind. The manufacturer's salesmen cannot take samples to the prospect's office or factory, and it is difficult to have his product shown at conventions, trade-shows, or similar gatherings of men whom he desires to interest in his product. Until recently salesmen depended upon their selling ability, aided by photographs, drawings, and data in regard to their goods. Where the prospective customer wished to see a machine in operation it was customary for the manufacturer to pay his travelling expenses to visit the plant, but this practice proved exceedingly expensive, and often took much, if not all, of the profit from the deal. The modern method is to have the salesman provided with a reel for demonstrative purposes. The salesman is equipped with a small portable projecting machine with which to show the reel, and in this way he is able to show his client all he wants to see, with the satisfaction to all concerned.

The estate agent can find no more effective way of selling property and lots than by the film. He saves the prospect much time and money, and gains his goodwill by not sending him on a fruitless journey.

City boosters need not compel people to imagine what they have to offer; the undeveloped territory or pleasure resort shown on the screen speaks for itself.

Societies in need for funds and other assistance can secure a better response to their appeals by acquainting the photo-playing public with the good work they are doing.

Shopkeepers in a fairly large way of business will find a short, local comedy or dramatic photo-play a big business-bringer. The above methods have been tried and proved, so you should find it much easier to obtain assignments.

How about forming an amateur photo-play society? When you come to think of the millions who attend the movies, it is surprising how few enthusiasts have combined to produce a simple local comedy or drama. All I can assume is that they have considered the amateur photo-play society far beyond the bounds of practical possibility. They have made a grave mistake in adopting this attitude, for, in proportion to the results attained, it is little or no more expensive than is dabbling at ordinary photography on a moderate scale.

Those with acting ability can figure in the cast, while the member possessing the most dramatic aptitude should be made the director. The talented weaver of stories would be the right man for scenario editor, provided he studied a book on photo-play writing and mastered the technique of photo-play construction. Last, but by no means least, you should do justice to the position of the camera-man.

If you can get the local photo-play shows to run your local productions, it will be a feather in your cap, but you may prefer to set up business on your own account. After having completed your first production, write all your friends and acquaintances, soliciting their support. Your own film-library will fit in like a glove, and you will not feel guilty of competing with the regular shows in your vicinity, and in this way you will be able to retain the friendship of the exhibitors and continue to supply their special needs.

You have, of course, the option of fixing your own territory, but I would recommend your not going beyond a radius of several miles. This will secure for your pictures a much more enthusiastic reception, because the spectators are especially

interested in local films, produced by local talent, amid scenes and things familiar to them.

Should you desire further clients, an advertisement in the local newspaper, setting forth the charms of a private motion-picture entertainment for social gatherings, clubs, societies, and lodges, will, no doubt, achieve the results for which you strive. Usually two pounds is charged for an hour's entertainment, comprising about four reels, and one pound for each additional hour. It is advisable to vary the films as much as possible, for it is variety on which the photo-play industry has been raised to its present prominent position.

Another field full of possibilities is in recording village pageants, local athletics, and the like. However good the printed page or photograph album may be in recalling the past, there is nothing to equal or excel, the motion-picture. The only way by which we learn history is through the historian's facile pen. Word-painting has its limitations, but the camera cannot lie. Who would not heartily enjoy our ancestors come to life again? Their quaint style of dress, the houses they lived in, and the customs that prevailed at the time would form a marked contrast to the way we live to-day. We should not think of the present, for when we have served our allotted span our successors will be as curious about us as we are about our ancestors.

Even to-day, when a well-known man or woman dies, his or her features have usually been caught by the motion-picture camera. The animated newspapers revive the scenes, proving how useful the motion-picture can be as a recorder of history.

Just because you live in a small town is no excuse for your not taking up topical work, for you are probably the only camera man in your own home town, and you are not up against the competition that prevails in the big cities.

The animated newspapers have correspondents stationed in most of the large cities, and in order to make a profitable connection you will probably have to give an exclusive option on your services, so far as the national field is concerned.

The news weeklies, circulating as they do from Land's End to John o' Groat's, want only negatives of national importance.

A local fair, while of great importance to Sleepy Hollow folk, would not appeal at all to Londoners. So, before covering a subject, ask yourself whether it will appeal to people irrespective of their location.

Don't, whatever you do, develop the negative before shipping it, for the film editor likes to be assured he is getting exclusive stuff; besides, he has better developing facilities, taking this highly skilled work off your hands.

Local topical work—and by this I mean events covered for local exhibitors—is in some respects different. The progressive exhibitor realises that nothing attracts a full house and produces so much permanent advertising as a good topical reel.

I do not advocate taking local topicals on the off-chance. Put the proposition up to some exhibitor beforehand, and obtain a definite assignment. The greater the number of prints in circulation the cheaper you can rent them out. Many an exhibitor, while favourably disposed toward having the exclusive rights for their town, cannot pay the exclusive price. Their maximum is around fivepence a foot, which should yield you a fair profit if hired out to a string of theatres in your vicinity.

The educational is but a short step. At present it is in great demand as "filler" material, although if the interest of the subject warrants it it is put out as a separate reel.

In operating in a fairly large city, expose film on the principal thoroughfare, the largest public building, church, park, theatre, and places of historic interest, and any interesting industries.

Even if you do not intend giving home entertainments with your film library, you will need a projection machine in order to run each reel prior to public exhibition, for editing purposes. The miniature projector has a shorter throw, but it is easier to manipulate, and does not consume so much current, besides effecting a three-figure saving.

By taking up motion-picture photography first as a hobby, with the ultimate object of making it your vocation, there is no reason why you should not eventually become known as the "motion-picture man" of your town.

ERNEST A. DENCH.

PRICE POLICY IN COMMERCIAL PHOTOGRAPHY.

{The following notes by Mr. G. D. Crain, Jun., in "American Photography" cannot be said to apply in equal measure in this country, where undoubtedly more commercial photography is done for smaller business propositions than in the United States. Nevertheless, the argument underlying them, viz., that a low price does not necessarily attract a certain class of customer, is one deserving of consideration, since, broadly, the conditions under which photographs are taken for commercial purposes are the same in the two countries. The article will, at any rate, serve to give a hint to the men newly starting to offer first-rate commercial work not to err in the direction of cutting prices. The initial advantage is problematical, and such prices may afterwards be a serious handicap.—Eds. "B.J."}

A GOOD many commercial photographers to whom the writer has talked in the last few months have the idea that while they are entitled to a good deal more money in the way of net profits than they are actually able to get, conditions in their field are so peculiar that it is out of the question to attempt to collect it. "The labourer and his hire," in their opinion, is a pretty theory which is entirely smashed in conflict with the practical conditions under which the photographer who is specialising in the business field is compelled to work. Consequently the average member of the trade is eking out an existence, paying most of his bills, and hustling like the mischief to collect outstanding accounts, while his line of credit at the supply house is generally strained to the breaking point. In other words, he is a good fellow and an excellent artisan when it comes to making pictures, but as a business man he is a colossal joke. That is, he would be a joke if he did not present such a pathetic figure in the business world.

The purpose of this article is not simply to criticise com-

mercial photographers for not getting as much money as they are entitled to for their work. Most of them agree with the idea, but simply fail in carrying it out. The object is to suggest that they are starting with the wrong premise, and are assuming something that isn't so—namely, that customers are not willing to pay for good work.

Not long ago the writer was in the office of a big furniture manufacturer. This man does a business of hundreds of thousands of dollars a year. He brings out new designs twice a year, and these have to be photographed and included in his catalogue, for the use of salesmen and merchants who handle his line. He displayed some of the new photographs which had just been made.

"Who took these?" he was asked.

The furniture man named a photographer in a city several hundred miles from his own, which, by the way, contains at least three photographers who could have handled that work very nicely.

"It cost a good deal to bring an outsider here and have him do the work," it was suggested. "Why didn't you have Blank, here in town, do the work?"

"Oh," said the manufacturer, carelessly, "these local photographers are too cheap. They are hardly up to this sort of thing. The other fellow certainly knows how to charge for his work—I just paid the bill!—but he delivers the goods on photographs."

Without stopping to debate the question of the value of specialisation, and hence the development of a reputation for being able to do a certain thing superlatively well, it is clear that in this case the local men had "queered" their own game by making a charge which was too far below that of their high-grade competitors in other cities to suggest that the quality of their work could possibly approximate what was wanted.

As the buyer of supplies in a certain big factory said not long ago, "In purchasing goods I seldom consider the low man, if he is very far out of line. I know that either he is not going to deliver the goods, and we will have trouble through the necessity of having to reject it, delaying us and causing him loss, or he will come out in the hole and be dissatisfied with the business. We want everybody who deals with us to make a legitimate profit, so that he can stay in business, give us just what we order, and find it worth while to go out of his way to give us service."

That is the modern way of doing things: not buying the very cheapest to be had, but seeking to combine service and quality in the right proportions by being willing to pay the price which these things command in the open market.

Photographs, especially those that are intended to serve a specific commercial purpose, lend themselves especially to the development of quality business, for the reason that the professional element enters into the proposition, and the customer can appreciate the fact that exceptional talent must be paid for accordingly. The photographer who would get a reputation for turning out good work, conversely, must learn how to charge a good price. The two go together, in most cases, and the average buyer has learned that he usually gets just about what he pays for.

The commercial artist who is doing a job at a price which barely allows a profit, but one which can be seen only with the aid of a high-power microscope, is going to try to cut the corners at every stage of the game. He has no choice in the matter. If he lost money on every order he would soon kick himself out of his job, and consequently the low-price work must be done at correspondingly low cost. Instead of taking a time exposure, even where it is desirable, he will make a flashlight out of it and beat it to the next job. Hurry-up methods in development and printing will be employed, in which quality may get some consideration, but probably not much. He will get out a photograph that will show the things that were to have been shown, in most cases, but which could have been improved upon vastly if more time had been taken.

That is "commercial" work in its worst sense. It is work which is obviously done just to get the money, and which, for that very reason, doesn't get the money in the amount which is gladly paid for photographic products which show thought and care and time-consuming painstaking—in other words, the professional, artistic aspect of the proposition.

The Elbert Hubbard—alias Emerson—sentence about the wood beating a path to the hut of the man in the woods, if he makes a particularly good line of mousetraps, is mostly

bunkum, but it contains a truth at that. Good work makes friends for itself and builds customers for the worker, but the live advertiser, who doesn't stop with publicity, but goes further and turns out quality products, is the man who will get the business and earn the profits while the chap in the backwoods will have been compelled to adopt a policy of watchful waiting for the customers who don't show up.

Yet, on the other hand, there is a certain commercial photographer who is of the type suggested by Fra Elbertus. He doesn't live in the woods, but in a large city. However, he has adopted the backwoods idea in his business methods, having a poorly located shop, no telephones, and being generally difficult of access. Yet he gets some business, has a lot of customers who would rather have him do their work than anybody else, and in a small way has established a fine reputation. The other commercial photographers in his community laugh at him because of his lack of aggressiveness, and yet they admire him because of his willingness to spend unlimited time in getting the correct results. On the one hand, he limits his capacity for getting business by his passive methods, and on the other he binds his customers with hoops of steel by turning out the sort of photographs that will help to sell goods.

The slap-bang system of doing work, coupled with keen business-getting ability and aggressive methods, will probably produce a reasonable degree of success, and a modest place can be won by the photographer who is so absorbed in his work that he forgets that he is in business to make money. But the palm must go to the man who combines business-getting, hustling ability with real quality methods, because that is the sort of photographer who will be able to get the prices that carry real profits.

Gouverneur Morris recently had a story in one of the popular magazines about several very alluring young women who, when fortune turned against them, converted their country place into a summer boarding establishment. In advertising it they decided to make it a bit exclusive, and to appeal to those who could afford to pay enough to make the game worth the candle. Consequently, one of the features of the announcement was, "Prices Rather High." The story told of the success of the plan, and of the very attractive and altogether eligible men who turned up in response to it, as well as the appeal of the photographs of the charming young women. The obvious moral for business men, including photographers who have become inoculated with the idea that they can't get the right amount for their work, is that there is a market which is appealed to by the announcement of prices higher than ordinary, because such an announcement connotes service out of the ordinary.

A great many people who have resources enough to be able to pay for anything they happen to want skip the bargains and are not classed among the bargain-hunters; and the man who wants to get their trade must get it by demonstrating that he has the goods, and that he is in a position to perform a professional service which is beyond the capacity of the rank and file.

The successful business establishment which is using photographs in its work wants good photographs. In spite of the beliefs of many photographers, it is willing to pay what they are worth. But it must first be convinced, by any individual solicitor, that he can really make the sort of pictures that are needed. After that kind of demonstration the prices will take care of themselves.

G. D. CRAIN, JUNR.

DEATH OF MR. J. T. CHAFFIN.—The death occurred at his home, 6, Hendford, Yeovil, on November 2, of an old and respected townsman in the person of Mr. John Tarver Chaffin, who for a long period of years had conducted a photographic studio. Mr. Chaffin, who died from heart failure, was sixty-three years of age.

His father, the late Mr. John Chaffin, studied photography in Paris, and on his return in 1862 opened a photographic studio at 6, Hendford. The son, after the death of his father in 1885, successfully carried on the business, took a great delight in his work, and won many honours both at home and abroad.

TRADE MARKS IN CHINA.

The growth of trade in photographic goods which the last few years have witnessed in the Far East, and especially in China, have brought to the notice of European manufacturers and merchants the difficulties which are encountered through the infringement of European trade marks in Eastern countries. In view of the complex legal conditions which prevail, we are quite sure that we are doing some service to the many firms in the photographic and allied trades by reprinting a most lucid and comprehensive exposition of the question, which takes the form of a paper read before the Shanghai Advertising Club of China by Mr. W. B. Kennett, of the British and American Tobacco Company (China), Limited, and a member of the Trade-Marks Sub-Committee of the Shanghai Chamber of Commerce, and published in the Chamber's "Journal." At the same time that this paper reached us there was also published in the "Board of Trade Journal" an abstract of a pamphlet of American origin dealing with almost the same questions as have engaged the attention of the Shanghai Club. We may therefore preface Mr. Kennett's paper by these notes.

An instructive pamphlet has recently been issued by a New York attorney, who has made a study of the trade-marks situation. He states that American manufacturers and traders must, for safety, seek carefully to observe certain rules if they wish to succeed in the export business. These rules are outlined as follows (and the advice given might be accepted by British firms):—

(1) They must register each and every trade-mark used by them upon their goods, in their own name, and in every country in which the goods are sold.

(2) Register the trade-marks before the goods are shipped abroad, and, if possible, before the marks are advertised in trade journals which will reach foreign countries.

(3) Where the same mark is used, or likely to be used, upon different articles of the same general class make certain that the registration covers all such articles.

(4) Where the same mark is used upon articles which are found in different classes, effect a separate registration for each distinct class.

The dangers of piracy, he states, may be classified chiefly as follows:—

1. *Actual Piracy.*—The registration by a foreigner of an unprotected, well-known, and valuable trade-mark, to the prejudice of the real owner who has neglected to protect his property. There are a great number of instances of this nature, and in most cases the real owner has been obliged to cease using his own mark in such country, or acquire the right to the use thereof from the registrant.

2. *Imitation and Counterfeiting.*—A trade-mark owner who neglects to register his marks abroad frequently finds his market flooded with inferior goods bearing imitations or counterfeits of his name or marks.

3. *Registration in Name of Local Agents.*—This is a frequent cause of trouble and expense in cases where disagreements have arisen, or new agents have been selected, as the mark is the property of the agent in whose name it was registered.

4. *Registration of Marks.*—Owners who allow the term for which a registration has been effected to expire without procuring a registration sometimes find that an unscrupulous trader has stepped in and secured the registration of the mark in his own name. This occasions serious loss in cases where marks have become well known and valuable through long use.

MR. KENNETT'S PAPER.

The subject of trade-marks is anywhere a very difficult and technical subject, and it must be particularly so in relation to China, where foreign nations have the privileges of extra-territoriality, and where so many different nationalities and systems of law are represented. The most I can hope to do is to give some general outline of the subject, and indicate some of the difficulties which have to be overcome in obtaining proper protection for trade marks in China.

Trade-Marks in General.

I will deal first with trade-marks, and will endeavour to give a definition of what a trade-mark is. Here I am, for the present, dealing with the broad principles of law which are in England called the "Common Law," that is to say, the law as apart from the specific law embodied in statutes.

An eminent English judge, Vice-Chancellor Bacon, described the general principles on which protection should be given to trade-marks as follows:—

"A manufacturer who produces an article of merchandise which he announces as one of public utility, and who places upon it a mark by which it is distinguished from all other articles of a similar kind, with the intention that it may be known to be of his manufacture, becomes the exclusive owner of that which is henceforth called his trade-mark. By the law of this country—and the like law prevails in most other civilised countries—he obtains a property in the mark which he so affixes to his goods. The property thus acquired by the manufacturer, like all other property, is under the protection of the law, and for the invasion of the right of the owner of such property the law affords a remedy similar in all respects to that by which the possession and enjoyment of all property is secured to the owners."

Another English judge used these words:—

"A man is not to sell his own goods under the pretence that they are the goods of another man; he cannot be permitted to practise such a deception, nor to use the means which contribute to that end. He cannot, therefore, be allowed to use names, marks, letters, or other indicia by which he may induce pur-

chasers to believe that the goods which he is selling are the manufacture of another person."

It will be seen, therefore, that a trade-mark has two principal functions:—

1.—To secure to the manufacturer the benefit of the goodwill which he creates in respect of an article, or brand of goods, which pleases the consumer and thus secures a large sale, and

2.—To secure to the consumer the right to obtain the goods he wants. It is on the faith of the trade-mark that the purchaser makes his purchase. The trade-mark means "You may take this mark as a warranty that this article is the same as that you have heretofore purchased, which has given you satisfaction."

It follows that apart from any question of registration of a mark, the law should, from the point of view of both the manufacturer and the consumer, prevent unscrupulous traders from copying or imitating trade-marks, for such conduct amounts to a fraud injuring both the manufacturer and the public; for it may be assumed that the public will in such cases be injured, as it is hardly likely that a manufacturer who is honest enough and capable enough to make goods of good quality would wish, or would consider it necessary, to put another trader's mark upon his goods in order to secure a sale for them.

I may mention here that a trade-mark does not necessarily mean that the goods on which it is used are goods manufactured by the proprietor of that mark. The person who selects or certifies goods may apply a trade-mark to them as a means of showing that he has selected or certified them, and he is entitled to have his mark protected just as a manufacturer is entitled to have his mark protected. The English Trade Marks Act of 1905 defines a trade-mark as follows:—

"A trade-mark shall mean a mark used upon or in connection with goods for the purposes of indicating that they are the goods of the proprietor of such trade-mark by virtue of manufacture, selection, certification, dealing with, or offering for sale."

I have pointed out that a trade-mark is for the protection of the public as much as the owner of the trade-mark, and from this follows the consequence that, according to English law, a trade-mark

may not be assigned except with the goodwill of the business connected therewith; that is to say, a manufacturer who has used a particular trade-mark for, say, a brand of meat extract, cannot assign that trade-mark apart from the goodwill of the business in such meat extract; if he did so the public might be misled into buying an entirely different product on the faith of the trade-mark. So far as registered trade-marks in England are concerned, a transfer of a mark without the goodwill of the business connected therewith cannot be made on the register of trade-marks, and if the mark were an unregistered mark, I take it that the effect of attempting to assign the mark without the goodwill of the business connected therewith would be to make the mark a "Common mark" in respect of which no protection could be claimed.

Passing-off Cases.

There is one class of cases which requires mention in connection with the general principles on which trade-marks are protected—that is to say, what are usually known as "passing off" cases. In these cases an actual trade-mark in the sense of a particular design or device, such as would be capable of registration as a trade-mark, is not necessarily imitated, but by general get up of the package in respect of similarity of size, colour, position of printed matter, style of type, and so forth, the package is made to look so much like the package in which another manufacturer's goods are sold, that an unwary or illiterate purchaser might be deceived. In short, the goods are so got up as to enable them to be "passed off" as another manufacturer's goods. Such cases are governed by substantially the same principles as those relating to trade-marks proper—that is to say, the law will restrain such abuses both in the interests of the original manufacturer and of the public.

Trade-Marks in China.

I will now pass on to consider trade-marks in China, and particularly trade-marks used by foreigners in China. We will assume that a British merchant carrying on business in China owns a valuable trade-mark which he has used in China for many years, and we will consider the risks of infringements which he runs, and the remedy which he has in each case.

There are three main classes of traders who may infringe the British merchant's trade mark:

- 1st, other Britishers.
- 2nd, foreigners other than Britishers.
- 3rd, Chinese.

With regard to the first class, infringement by traders of the same nationality as the owner of the trade-mark, there is no great difficulty, for, if a Britisher in China infringes another Britisher's mark, or passes off his own goods as other people's, the injured merchant can take action against the offender in the British Court, and will have practically the same remedies as he would in England. I assume the position would be the same in the case of an American citizen bringing an action against another American citizen in the United States Court, or a Frenchman bringing an action against another Frenchman in the French Court.

Reciprocal Agreements Between the Great Powers

With regard to the second class, namely, infringement by a foreigner of another nationality, certain of the Great Powers have entered into special arrangements between themselves, whereby each nation agrees to give protection against infringement, by its own nationals, of the trade-marks of the nationals of the other nation used in China. Great Britain has entered into reciprocal arrangements of this nature with Belgium, Denmark, France, Germany, Italy, the Netherlands, Portugal, Russia and the United States respectively. These agreements were carried out by the exchange of Notes between the respective nations mentioned, made in the years 1903 to 1906.

The condition on which protection is given is, the mark for which protection is sought must be registered in the country from the courts of which in China protection is sought. Thus, if a British subject seeks protection in the American Courts here against infringements of his trade-mark by an American citizen in China, he must show that he has registered his trade-mark in the United States, while an American citizen seeking protection in the

British Court against infringement of his mark by a Britisher in China must show that he has registered the mark in the United Kingdom. This arrangement is somewhat unsatisfactory, because it practically compels a foreign trader in China to register his mark in all the countries named, in order to obtain the most complete protection he can in China.

Infringement by Japanese.

You may have observed that Japan was not among the countries named as having entered into reciprocal agreements with Great Britain for the protection of trade-marks in China. There is no such agreement between Great Britain and Japan. It is generally understood that Japan was approached with a view to entering into a similar agreement, but that she declined to do so. A very interesting question arises in this connection—although Japan did not make a reciprocal agreement with Great Britain, she did make such an agreement with the United States by the Treaty of 1908. The particular provisions of this Treaty are as follows:—

Article 1.—Inventions, designs and trade-marks, duly patented or registered by subjects or citizens of one High Contracting Party in the appropriate office of the other Contracting Party shall have in all parts of China the same protection against infringement by subjects or citizens of such other Contracting Party as in the dominions of such other contracting party.

Article 3.—In case of infringement in China by a subject or citizen of one of the two High Contracting Parties of any invention, design, trade-mark or copyright entitled to protection in virtue of this convention, the aggrieved party shall have in the competent territorial or consular courts of such Contracting Party the same rights and remedies as subjects or citizens of such Contracting Party.

Now, in the Treaty of Commerce and Navigation between Great Britain and Japan entered into in 1894, there is the following clause:—

The High Contracting Parties agree that, in all that concerns commerce and navigation, any privilege, favour or immunity which either contracting party has actually granted, or may hereafter grant, to the Government, ships, subjects or citizens of any other State, shall be extended immediately and unconditionally to the Government, ships, subjects or citizens of the other Contracting Party; it being their intention that the trade and navigation of each country shall be placed in all respects by the other on the footing of the most favoured nation.

The question is, whether the effect of this clause is to give to British merchants in China the same protection and rights against infringement of their marks by Japanese as American merchants would have in similar circumstances. It will be observed that the article of the Treaty says, "in all that concerns commerce" any privilege granted to the citizens of any State shall be immediately and unconditionally extended to subjects of Great Britain. The protection of trade-marks is surely a matter of commerce, and it may, therefore, well be argued that, notwithstanding the fact that there is no express reciprocal agreement between Great Britain and Japan as to the protection of trade-marks in China, British merchants, by virtue of the "most favoured nation" clause above quoted, nevertheless have exactly the same rights in this respect as American merchants have under the above quoted Treaty. It is a very interesting point, and it might possibly be worth while attempting to get protection upon this basis in the case of persistent infringement of a British merchant's mark by Japanese.

There is another method by which foreigners in China may get partial protection against Japanese infringements: that is, by registering their marks in Japan. Such registration would entitle them to stop the manufacture of goods bearing an infringing mark in Japan for export to China, although it might not stop the production of goods bearing an infringing mark by Japanese in China.

There is yet another method by which trade-mark owners in China may sometimes get protection in respect of any extensive sale in China of goods got up in imitation of their goods and manufactured by Japanese—that is to say, by taking proceedings against any Chinese dealer who sells such goods. Naturally, wherever it is possible, one likes to attack an evil at its source, and no one would willingly take proceedings against a shopkeeper for selling offending goods if he could find and take proceedings

against the manufacturer; but where the manufacturer cannot be found, or where by reason of his nationality proceedings cannot be taken against him, it is sometimes necessary to take proceedings against the man who actually sells the goods, and an injunction can be obtained against him, which will serve as a warning to him and to all other retailers to avoid dealing in imitation goods.

Infringements by Chinese.

I will now deal with the third class of infringement—namely, infringement by Chinese:—

By the Treaty made between Great Britain and China in 1902, the Chinese Government undertook to afford protection to British trade-marks against infringement or imitation by Chinese subjects. The Chinese Government further undertook that offices should be established under the control of the Maritime Customs, where foreign trade-marks might be registered on payment of a reasonable fee. By the Treaty with Japan of 1903 China is bound "to make and faithfully enforce such regulations as are necessary for preventing Chinese subjects from infringing registered trade-marks held by Japanese subjects." Of course, all foreign nations enjoying extra-territoriality and the benefit of "the most favoured nation" clause as to agreements with China are entitled to the same privileges and protection.

Some years ago there was established at the Customs Office in Shanghai a Bureau for Provisional Registration of Trade Marks, but it cannot be said that anything in the nature of a registration of trade-marks has been established, for the Bureau simply accepts for filing any trade-mark, or alleged trade-mark, which is presented, and there is no investigation, advertisement or other procedure which notifies the public that an application has been made to register the proposed mark, or gives interested traders the right to object, such as is in force wherever there is a proper system of registering trade-marks. In fact, the Bureau simply files trade-marks which are presented to it, and such filing cannot, obviously, give the merchant who files the mark the title to it, as there may be many conflicting marks already in existence and even on the file, which would prevent registration if the usual procedure of examination and advertisement took place.

Nevertheless, although there is no proper registration of trade-marks in China, foreign traders are not entirely without remedy in case of infringement of their marks or imitation of their packages by Chinese. I have already endeavoured to explain that the "passing off" of goods as those of another manufacturer is a species of fraud, which, apart from any statutory enactment, is so contrary to public welfare that in any country having a system of law it will be restrained on general principles. I presume these principles would apply in any court in China, and they certainly are applied in the Mixed Courts in the Foreign Settlements where, naturally, most of such cases are likely to be dealt with.

Mixed Court Cases.

There have been two recent trade-mark cases in the Mixed Court in Shanghai. One very interesting case was that brought by Messrs. Burroughs Wellcome and Company against the Nanyang Medical Company in respect of the sale of goods got up in close imitation of the plaintiff's well-known toilet article called "Hazeline Snow." That was a case where the shape and design of the package, the colouring of the design, the position of the printed matter, and the method of packing made it clear that the article produced by the defendants was got up in the way it was for the purpose of enabling it to be "passed off" on an unwary purchaser as the plaintiff's well-known article. There were, of course, minor differences in the packages, as there usually are in such cases, but it would be impossible for anyone comparing the two packages to have any doubt in his mind that the defendant's package was produced by someone having before him the plaintiff's package, and intending to produce a package so like the plaintiff's package as to enable the imitation goods to be passed off on an unwary purchaser as the original production. In this case the court granted an injunction against the defendants, and ordered delivery to the plaintiffs of all the imitation goods in the defendant's possession, and an account of all the profits the defendants had made by selling the imitation goods. You will see, therefore, that the penalty for conduct of this sort is a substantial one, and it is to be hoped that this case will have a deterrent effect upon other producers of imitation goods.

Another case recently before the Mixed Court in Shanghai was that of Messrs. A. R. Burkill and Sons against Shun Tah, in respect of the sale of soap got up in such a manner as to enable it to be passed off for a soap manufactured by W. Gossage and Sons, Ltd., for which the plaintiffs are agents in China. This was one of the cases in which the proceedings were taken against the retailer, as it was apparently impossible to ascertain who was the manufacturer, or to bring him before the court. The court was satisfied that the soap was so got up as to enable it to be passed off as the soap sold by the plaintiffs, and an injunction was granted prohibiting defendants selling the soap for the future.

Both these cases were civil cases. It is also possible to take criminal proceedings in the case of deliberate manufacture and sale of counterfeit goods. Within the last three years convictions have been obtained in several cases where cigarette wrappings, including the manufacturer's name, were counterfeited in the most deliberate and complete manner.

It will be seen from the cases that I have quoted that foreigners are not entirely without remedy in the case of imitation of their marks or packings by Chinese, and that the undertaking given by the Chinese Government to Foreign Powers as to protection of trade-marks belonging to their subjects in China is, to some extent, carried out. The undertaking, however, cannot be properly and completely carried out, nor can full protection be given to trade-marks in China, until a trade-mark law has been promulgated by the Chinese Government with the consent of the Foreign Treaty Powers, which law should provide a proper register for trade-marks, in which both Chinese and foreigners can register their marks. It is obvious that, as extra-territoriality exists in China, such a law can only be promulgated and made binding upon foreigners as well as Chinese, if the various foreign governments concerned agree upon the draft law.

During the past twelve or fourteen years this question has been brought up for consideration from time to time, but no scheme acceptable to all the Foreign Powers has yet been produced. The blame, therefore, for the lack of a proper trade-mark law cannot be put upon the Chinese. There are many difficult questions which will have to be settled in connection with the proposed law, of which the principal one is the question as to the right of registration where there are rival claimants for registration of the same mark or of conflicting marks. It is obvious that the filing of a mark at the Bureau for the Provisional Registration of Trade-Marks, which I have mentioned, cannot be regarded as giving the person who filed it the right to the mark, because, possibly, he had no right at all to file it, and he may have deliberately filed it, knowing that it belonged to another. In fact, it is believed that, at the time the Bureau was opened, large numbers of well-known marks were filed by persons having no right whatever to them. It is obvious that such persons cannot be given rights by reason of such unjustifiable action.

I think that probably most of us will agree that the fair and proper test should be priority of *bona-fide* user of the mark in China; but the user must be *bona-fide* user, and in cases where a trader has taken some well-known mark, used extensively, for example, in the United States, and has put out goods under such mark without having any right whatever to do so, he ought not to be entitled to obtain rights to such mark in China so as to prevent the original owner of the mark abroad from sending goods here, unless he—that is the trader who has used the mark in China—can show that he has used it for a long period, without protest or objection; if he can show this, and can show that he has used the mark in a substantial and open way, then he may be entitled to have the mark registered, as it may be assumed that the original owner of the mark abroad has no wish or intention to use the mark here in China. In fact, to put the whole thing into a few words, it is *bona-fide* user which should be the test, not improper user.

Although, therefore, there are difficulties in formulating a law which will be acceptable to China and to all the nations concerned, these difficulties, I think, are not insuperable if they are approached in a reasonable way, with a view to meeting an urgent necessity, and not with a view to giving any one nation an unfair advantage over another.

It should be in the interests of every nation represented here

in China to have put into force a proper system of registration of trade-marks and enforcement of protection to trade-mark owners, such as is usually given in civilised countries. We know that the condition of things existing at present gives the nationals of one nation unusual opportunities to imitate trade-marks with comparative impunity, but I cannot think that such an advantage can do any real good to that nation in the long run. After all, the imitation of a trade-mark, or the packing of the goods of another trader, is a mean business: it carries with it the confession of inferiority, because there is no need for a competent and honest manufacturer to endeavour to sell his goods as those of another manufacturer. Any nation whose subjects make a habit of this class of mal-practice must earn a reputation which, in the long run, cannot fail to outweigh any temporary advantage which some of its subjects may at present obtain by unscrupulous methods.

In the near future the question of a trade-mark law for China must again come up for consideration. I think that this time it must be definitely dealt with, for trade is extending in China and more trade-marks are getting into use almost daily. It is already high time that means to record rights to trade-marks was provided, for the longer the present state of things continues the more difficult will be the problems which will have to be dealt with when registration begins. We must hope that all nations concerned will take a large view of the position, and that none will let any private advantages or interests, not based on the broad and world-wide principles of commercial morality, stand in the way of reform and progress.

W. B. KENNETT.

New Apparatus, &c.

The British Anschutz Focal-Plane Camera. Made by Messrs. R. E. Peeling and S. Van Neck, 4-S, Holborn Circus, London, W.C.

As every Press photographer will confirm, a camera of ex-enemy manufacture which for many years before the war was the most popular instrument among pressmen was that known as the Anschutz, or, more commonly, as the Goerz-Anschutz, in reference also to the name of its maker. The camera was the pioneer among those of the focal-plane type, and undoubtedly retains its wide popularity among Press photographers owing to its general excellence of construction, and particularly the reliability of its shutter. Messrs. Peeling and Van Neck have, therefore, done a good thing in taking up the manufacture of this instrument, and in this connection deserve a word or two by way of introduction to the general photographic public, to whom perhaps they are not so well known as in trade photographic circles. Both are mechanics of long and special training in photographic apparatus, one of them in pre-war days with the Goerz firm, and the other as an expert repairer of all descriptions of camera. Their association in offering photographers the Anschutz camera is, therefore, particularly fortunate, since together they embody an experience not merely of this instrument but of those weak points in focal-plane cameras which it is desirable to avoid. Thus the Anschutz camera has been issued with some modifications which remove one or two defects of the German-made instrument. For example, the back frame of the new camera is made of aluminium instead of the thin and easily breakable wood employed in the German model, and the front main panel is made without any division above and below, so that it affords the most secure holding of the extending struts. Moreover, the best mahogany has been used for the wood parts in place of the more brittle ebonised wood, and the pneumatic release of the shutter has been replaced by an Antinous fitting.

In the important matter of the shutter the British makers have quite rightly, as we think, adopted the ordinary instead of the self-capping type. Their experience, which no doubt most Press photographers will corroborate, is that the non-self-capping shutter, owing to its less complicated construction, is less liable to get out of order, and every user of the camera would certainly prefer extra reliability to the very problematical and infrequent advantage of self-capping. The shutter-blind is of the double-slit pattern, one slit being of fixed width, namely, the full width of the plate, and the other adjustable by a very simple movement

applied to the blind itself. The wide slit is used for slower instantaneous speeds and for bulb and time exposures, the other serving for the most rapid exposures. The two slits are kept quite separate in use by a special catch, but one or the other is brought into operation by pressure on this catch from a stud placed on the left-hand side of the camera. With the adjustable slit set at a medium width, variation in the spring tension of the shutter thus allows of the operator giving exposures from 1/10th to 1/120th of a second without any alteration of the slit-width, the slower speeds being obtained with the fixed slit, and the more rapid ones with the narrower adjustable slit. Since such a range corresponds with the requirements of a large proportion of subjects, it may be said that alteration of the slit-width is necessary only for subjects of very rapid movement, such as sports, etc. Outside adjustment of the shutter to instantaneous (I) or bulb (B) is provided, and with the shutter at the "bulb" setting the exposure can, if desired, be begun by a sharp rapid touch on the release trigger, the blind then remaining open until the trigger is again pressed. In other words, the "bulb" setting provides for both "bulb" and "time" exposures. A further good feature of the shutter is the close mounting of the blind to the true focal-plane or surface of the plate. Particularly with rapid exposures (narrow slit), excessive separation of blind and plate greatly reduces efficiency of exposure. In the British Anschutz the blind appears to us to be as close as it is possible to put it in a plate camera.

In other respects the camera does not call for special comment, since its chief other features are those which have long been familiar to the users of the ex-enemy model. The English makers, however, are supplying it with plate-holders of the solid Shew pattern, in which two plates, back to back, with a separating card between them, are inserted at the base of the holder, the aperture in which is then closed by a rebated end-piece fitted with a spring. The device is one which facilitates rapid loading, and, moreover, holds the plates beyond any possibility of their slipping out of position.

The new camera is supplied with three of these slides and stout brown leather case at the price of £30 in 5 x 4 size, with 6-in. f/4.5 anastigmat. The makers have chosen the new model T.T. and H. "Aeroplane" anastigmat as the standard optical equipment, although there may be some delay in supplying this lens. Earlier deliveries of the Anschutz may, therefore, possibly be fitted with other lenses. The outfit is certainly one which, after the closest inspection of it, we can recommend to those requiring an instrument for Press or similar work.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 15.

Manchester Amateur Photographic Society. "Happy Japan, Garden of Giltter." H. G. Allen.

MONDAY, NOVEMBER 17.

South London Photographic Society. "The Domestic Fly, its Habits, Structure and Menace to Health." Dr. G. H. Rodman.
Dewsbury Photographic Society. "More About Lantern Slides." H. Potter.
Widewater Photographic Society. "Home-Made Apparatus."
Bradford Photographic Society. Members' Print Night. Sale of Apparatus.

TUESDAY, NOVEMBER 18.

Royal Photographic Society. "The Story of the Cuckoo Spit." Dr. G. H. Rodman.
Hackney Photographic Society. "Thames Pictures, from Negatives Taken during 1919."
Chelsea Photographic Society. "Some of My Pictures." T. H. B. Scott.
South Glasgow Camera Club. Lantern Slide Competition and Lectures.
St. Albans Photographic and Scientific Society. "Demonstration on Enlarging." F. Wintaker.

WEDNESDAY, NOVEMBER 19.

Croydon Camera Club. "Algeria." Dr. C. A. Swan.
North Middlesex Photographic Society. "Ravens." J. F. Nisbet.
Edinburgh Photographic Society. "Gum Picturist Process." R. Thomson.
Dunbarton Amateur Photographic Association. Portraiture Competition.
Patrick Cairns Club. "Development of Plates and Film." F. V. Taylor.
South Suburban Photographic Society. "Newton's Flashlight Paper." G. W. Green.
Halifax Scientific Society. "Eola god Nectans" from P.G.I. Prints. B. Wade.

THURSDAY, NOVEMBER 20.

Liverpool Amateur Photographic Association. "Cruise to the Western Fjords of Norway." Rev. R. E. de Wolf.
Hammer-smith (Hampshire House) Photographic Society. A. P. Slides—Affiliated Slides.
The Camera Club. "The Spider—its Formation and Habits." Dr. G. H. Rodman.
Richmond Camera Club. "Carbon Printing." A. C. Braham.

Chelsea Photographic Society. "The Thames," with colour slides. J. McIntosh.
 Brighouse Photographic and Naturalist Society. Y. P. U. Slides and Prints.
 Aston Photographic Society. "Lantern Slide Making." W. F. Carter.
 Wimbledon Camera Club. Demonstration, "Satista." T. W. Derrington.
 Hull Photographic Society. "Round Yorkshire." Rev. W. Hay Fea.
 Birmingham Photographic Society. Annual General Meeting.
 Radley and District Photographic Society. "Building the Picture." Messrs.
 Willey and Slater.

FRIDAY, NOVEMBER 21.

Royal Photographic Society. "Scorpions, Spiders, and their Kin." F. Marting-Duncan.
 Dennistown Amateur Photographic Association. "Development." R. Wallace.

THE ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 11, the President, Dr. C. Atkin Swan, in the chair.

The President delivered his annual address to a very small audience. Armistice anniversary celebrations may perhaps have been the cause of the insignificant attendance of members, but it could not go unremarked that not one of the members of the council of the Society was present. Dr. Swan disclaimed any intention of making his address a learned disquisition upon some technical subject, but preferred to deal by way of retrospect and looking forward with a number of topics of general and specific interest to members of the Society. He briefly referred to the defeat of the enemy in the several branches of photographic manufacture, and turned to consider the programme which the Society had carried out during the session which comes to an end early next year. He said that the formation of the Scientific and Technical Group within the Society was a step which it was most necessary to make in order to deal with the study and advancement of the many special branches of photography which had come into existence during the past twenty years. Answering objections to the formation of such a Group which he had heard, he pointed out that the special work of the Group would be carried on by means of the extra subscription paid by Group members, and he was quite sure that there was no ground for dissension in the Society on any score. The formation of the Group had had his hearty support, and he hoped that it would also receive that of the general body of members.

On the proposition of Mr. John H. Gear, seconded by Mr. J. W. Lamb, the thanks of the meeting were heartily accorded to the President.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

A MEETING was held at 116, Hanover Street, Edinburgh, on Monday, November 3, 1919, at 8 p.m. Present: Misses Grey, Ead-ington, D'Arcy, Messrs. E. Drummond Young, Johnston, Swan Watson, Laing, Norman Thomson, John Thomson, Campbell Harper, Fergusson, Philip, Moffat, Lauder, Bambrick, George Balmain, and Macalpine. Mr. E. Drummond Young in the chair.

Apologies for absence were intimated from Messrs. Ayton, Drummond Shiels, and Barrie.

The minutes of the last meeting were read and approved of.

The proposal to hold a professional photographers' exhibition in Edinburgh next year was discussed. The Chairman intimated that unless twelve members supported the proposal it could not be proceeded with, and in the meantime only nine had indicated their willingness to do so. The feeling of the meeting was that once the scheme was gone on with other members would co-operate, and it was accordingly resolved to continue the matter until the next meeting in December. In the meantime it was arranged to approach some of the other members and endeavour to secure their support.

Mr. Swan Watson reported that he had had an interview with Principal Laurie, of the Heriot-Watt College, in regard to the position of apprentices under the Scottish Education Act. The Principal had stated that the College had at present no equipment or apparatus for the technical teaching and training of photographers' apprentices, and that, in any event, the Act would not be in force until two years subsequent to a date to be fixed by Government. The meeting accordingly resolved to disregard the Act until it was made compulsory. The matter was recommended to the committee to consider the terms of the proposed apprentice agreement, and to submit the same to the meeting of the society on January 5 next for approval and adoption.

The question of the charge for electricity power was next

considered. It was pointed out that photographers in other towns, such as Glasgow and Carlisle, were charged a power rate for portraiture and printing, and it was considered that a similar concession should be obtained by photographers using electricity in Edinburgh. A letter addressed to Mr. Drummond Shiels by Mr. Hannah, of the town clerk's department, was read to the meeting, in which it was stated that a special rate of 3.15d. for the first 5,000 units per annum and thereafter 2½d. per unit, with a minimum charge of £2, had already been conceded to photographers for printing process only. The feeling of the meeting was that the members using electricity had a grievance, and that some steps should be taken to remedy matters in view of the considerable amount of electricity consumed and the privileges held by photographers in other towns. The present time was, however, considered unsuitable to approach the Town Council in the matter, seeing that electricity is at present rationed and the possibility of changes in the personnel of the Electricity Committee. It was resolved to delay further consideration of the matter until the January meeting.

It was agreed to hold the annual dinner on the first week of December, and the following members were appointed a committee to carry out the arrangements:—Messrs. Young, Moffat, Macalpine, and Balmain.

This concluded the business of the meeting.

CROYDON CAMERA CLUB.

ON Wednesday in last week, November 5, the "annual" dinner was held, the first since 1913. The president, Mr. John Keane, formed the centre of a large company (numbering between sixty and seventy) of members and guests, the latter including Dr. Atkin Swan, Messrs. F. C. Tilney, James A. Sinclair, T. H. B. Scott, W. L. F. Wastell, and G. E. Brown. Letters of regret at inability to be present were received from Messrs. R. Child Bayley, F. J. Mortimer, W. H. Smith, and S. H. Wratten. It was quite a gathering in the spirit of the old pre-war days, and Mr. Keane appropriately echoed the feeling of those present when he claimed that apart from the work which members of the club had carried out by way of contribution to the winning of the war, the Club as a whole had manifested the national spirit of dogged persistence by keeping its meetings going without interruption. It was that spirit, he said, which in a hundred different walks of life had preserved the country throughout the circumstances of the past five years. In felicitous terms he proposed the toast of "The Guests," contributing a complimentary thumbnail sketch, so to speak, of each in turn. Croydon can do a thing like this in the happiest manner, and it appears to be a tradition of its presidents to be able to express the most honeyed opinions of those to whom it offers its generous hospitality. An attempt perhaps to dissipate the idea that in the ordinary way plain speaking between its own members is ever taken to the point of simulated rudeness. Dr. Atkin Swan and Mr. T. H. B. Scott replied to the toasts, each in his accustomed and delightful style of humour. Other toasts interspersed a most enjoyable evening, the pleasure of which owed a good deal to the musical and narrative performances of Mr. Tilney, Mr. H. P. C. Harpur, Mr. Aokroyd, Dr. Swan, and the Rev. Le Warne.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

THE members of the society had a very good time at Southport on October 28, when the whole of the day was devoted to business and pleasure. Mr. F. Read, the popular and enthusiastic treasurer of the society, had control of the arrangements, and, needless to say, under his able guidance they were perfect. Those who, like himself, were devotees of golf met at the railway station early in the day, and spent the whole of the morning until lunch time on the links, whilst those kindred souls who preferred the homeliness of the smoke-room to the excitement of the golf links entertained each other in the delightful lounge of the Queen's Hotel, which, through the kindness of the management, had been placed at the exclusive use of the members of the society.

The business side of the day commenced at 2.30 with a committee meeting, a large number of committeemen from the various parts of Lancashire being present.

In the absence of the President of the society, Mr. F. Kenworthy, the committee unanimously voted Mr. F. Read into the chair, and a very able chairman he made.

A great amount of important business was dealt with in the hour devoted to this meeting, and all the important points raised were fully discussed at the subsequent general meeting.

The general business meeting, to which all the members had been summoned, commenced at 3.30, Mr. F. Read again presiding.

The Secretary having read the minutes of the committee meetings held since the last general meeting, a number of questions arising out of these minutes were discussed, amongst the most important being Assistants' Specimens, as already reported in the "Journal" some time ago, which suggested that the assistants be allowed a set of specimens before leaving the employment of any member, these specimens to be secured from time to time by the assistants and submitted to the employer, and if the employer was satisfied that they were the work of the assistant he (the employer) should sign the specimens accordingly and forward them on to the secretary of the society to be endorsed by the seal of the society. On the assistant leaving the employer a covering letter should be given to each assistant intimating that the specimens submitted were the work of that assistant. The letter should also bear the crest of the society, and it was therefore decided to recommend to the whole of the members the adoption of this system at as early a date as possible.

A very lengthy discussion took place on the important question of the price of bromide paper, and in the course of the discussion it was pointed out that, although the paper restriction Order No. 31918 had been withdrawn on April 30 this year, making it possible for all paper bases to be imported, as in pre-war days, yet no attempt had been made on behalf of the manufacturers to make any satisfactory reduction in the price of bromide paper.

Another important question discussed by the committee was that of apprentices, and it was the general feeling of those present that at the next general meeting of the society the members should come prepared to thoroughly thrash out this question.

Mr. W. H. Huish, the secretary, had undertaken to give a paper at the next general meeting on the question of "Industrial Councils," and it was thought that, in conjunction with this paper, the apprentice question could be very fully gone into.

It was arranged to hold the next general meeting at the George Hotel, Preston, on Tuesday, November 18, at 5.30, and the secretary was instructed that, when sending out the notices regarding this meeting, he should invite the members to come prepared to discuss this important question.

A suggested design for the diploma of merit in connection with the recent exhibition held at Blackpool was submitted to the committee, but not approved, and it was decided to offer a prize of £1 to the member who could send in the best design, the same to be in the secretary's hands before the next general meeting.

At 5.30 the members sat down to tea, after which a social gathering was held. In the absence of a number of well-known artists, who had unfortunately been prevented from attending, Miss Marie Philpott and Mr. G. Mills kept the company entertained and amused until 9.30, when most of the members were obliged to leave in order to get their trains home.

Commercial & Legal Intelligence.

PRICES OF MOUNTS.—In the Shoreditch County Court on Tuesday, November 11, before Judge Cluer, the hearing was resumed and concluded of the action in which Messrs. O. Sichel and Samuelson, of 52, Bunhill Row, E.C., cardboard merchants and photographic material manufacturers, sued Mr. N. M'réches, of Kingston Studio, 27a, Market Place, Kingston-on-Thames, to recover £5 16s. 10d. for 1,000 cardboard photographic mounts. At the first hearing of the action the plaintiffs' traveller said he took the order for 500 of each size of two mounts. No price was fixed, as it was expressly stated by him that cardboard manufacturers would not give any fixed prices at this time, August, 1918. The defendant denied giving the order, and also protested that anyway the price was very unreasonable. The hearing was adjourned for the plaintiffs to prove by the

manufacturers' prices that their price was reasonable. When the hearing was resumed Mr. McDonald appeared as counsel for the plaintiffs, and he explained that as he was not present on the first occasion he proposed to go over the case again. Judge Cluer positively refused to allow the case to be reopened and thus delay the other work of the Court.—Mr. McDonald: Your honour will remember it was adjourned for proof that the price charged was fair.—Judge Cluer: What am I here for but to remember these things?—Mr. Fordham, of the firm of Messrs. Fordham and Co., said they printed the cardboard photographic folders. There were 500 each of two sizes, 6 ins. x 4 ins. and 8 ins. x 6 ins., and the charge was £1 7s. 3d. in all.—Mr. McDonald: And would a charge of £5 16s. 10d. be an unreasonable one under the circumstances?—Witness: Do you want me to say from the point of view of what a manufacturer usually gets as a profit or as a profit by the plaintiff?—Judge Cluer: I think the point is fine. It appears to have been an addition of a little more than 25 per cent.—not an outrageous profit in these days.—This closed the plaintiffs' case, and the defendant then said he disputed the giving of the order altogether. What happened, he declared, was that Mr. Coomb, the traveller, called upon him and showed him a number of mounts. Defendant was pleased with some of them, and asked for the prices, but the traveller said he had forgotten them. Defendant asked him to let him know, as, if the price was right, he would order 1,000 each of them. The next that happened was a month after, when he received the 500 each of two sizes. As he knew nothing of the price, and had not ordered them, he rang up Mr. Sichel, and asked him what he should do about them. Mr. Sichel told him to keep them till the traveller called, and he did so. When Mr. Coomb arrived he pretended that he thought he had taken an order, and asked him if he would make an offer for them. Defendant said he hardly could as they were asking twice as much as other manufacturers. Mr. Coomb finished by leaving them there.—Judge Cluer: Why didn't you send them back?—Defendant: I did send them back.—Judge Cluer: Not until nine months after. It may be that there are travellers who carry on sharp practices, and declare they have taken orders which they have not, in the hope of being able to induce the person to accept them; but I have no reason to suppose so in this case. He says you gave him the order, and I see no reason to doubt it; you kept the goods for nine months after.—Miss Bailey, an assistant in the shop, was then called, and said she was present when Coomb, the traveller, was showing off the cardboard mounts. She was quite positive that when he was asked the price he said he did not know, and promised to send it on, so that an order might be arranged.—Judge Cluer: Did he say why he did not know the price?—Witness: No.—Judge Cluer: Well, he has told us why that the manufacturers were not giving fixed prices at the time; a perfectly reasonable reason. I have come to the conclusion that an order was given, and my verdict will be for the plaintiffs. Judgment was entered accordingly, with costs. On the first hearing the plaintiffs had to pay to the defendant 12s. 6d. costs, and this amount will be set off.

THE AFFAIRS OF FRANK SOWARD, 32, CONISTON ROAD, MUSWELL HILL, N., who had been interested in two companies, called Colourgraphs, Ltd., and Photocol, Ltd., have previously been reported in these columns, and on November 4 they came before Mr. Roger Mellor at the London Bankruptcy Court upon the hearing of debtor's application to approve a proposal providing, *inter alia*, for the payment of a composition of 5s. in the £ to his unsecured creditors. He failed on July 3 last, and, in the opinion of the Official Receiver, the proofs of debt and probable claims aggregate £867, whilst the assets were estimated by the debtor to realise £9. He acted as a director of Photocol, Ltd., until June last, and he attributes his insolvency to his association with another person, estimating his loss in that connection at £950, of which £450 represents the amount of cash that he provided for financing the two companies mentioned.

When the case was called on for hearing the Official Receiver reported that the debtor was not in attendance, neither had the sum necessary to pay the composition been lodged with him.

In the circumstances his Honour refused to approve the proposal.

LEGAL NOTICES.—Notice is given of the dissolution of the partnership between John William Heawood and Joseph Watson, lately carrying on business as photographers at Station Road, Hinckley, Leicester, under the style of Heawood and Watson. John William

Heawood retires, and the business is being carried on by Joseph Watson, who will receive and pay all debts.

NEW COMPANIES.

SUNBEAM PHOTO, LIMITED.—This private company was registered on October 31, with a capital of £1,000, in £1 shares, to take over the business of a photographer carried on on the foreshore at Margate under an agreement between F. L. Peltman and Martha E. Whitrose of the one part and the corporation of Margate of the other part. First directors: F. L. Peltman, 2, Cliffside, Fifth Avenue, Margate, contractor; T. Head, 13, Godwin Road, Margate, photographer. Registered office: 12, Dalby Road, Margate.

SCIENTIFIC AND PROJECTIONS, LIMITED.—This private company was registered on November 3. Capital, £10,000, in £1 shares. Objects: To carry on the business of manufacturers of and dealers in cinematograph, photographic, scientific, philosophical, electrical, and optical instruments, etc., and to enter into an agreement with F. W. Larkins and S. R. Bailey. The first directors are: C. Fairweather, 37, Hindes Road, Harrow (chairman); A. S. March, 59, Eagle Road, Wembley; and F. W. Larkins, 21, Shrewsbury Road, New Southgate, N. Registered office: 5, Crawford Passage, Farringdon Road, E.C.

GOSNAY ADVERTISING COMPANY (1919), LIMITED.—This private company was registered on November 5, with a capital of £10,000, in £1 shares. Objects: To take over the business of advertising and photographic contractors, printers, zinc and wood engravers, etc., lately carried on by the Gosnay Advertising Company, Limited, at 6 and 7, Little White Lion Street, Long Acre, W.C., and to enter into an agreement between said old company of the first part, W. J. Mawrey, F. A. Wood, and H. J. Jewell of the second part, Odhams, Limited, of the third part, and W. J. B. Odham of the fourth part. The subscribers (each with one share) are: W. J. B. Odham, 93-4, Long Acre, W.C., director and publisher; J. S. Elias, 93-4, Long Acre, W.C., printer and publisher. The first directors are: J. S. Elias, W. J. B. Odham, and F. Mills. Registered office: 93-4, Long Acre, W.C.2.

News and Notes.

THE STEREOSCOPIC SOCIETY.—After twenty-six years of successful working, this society has now inaugurated a branch in the United States, and includes in its fortnightly portfolios interesting slides submitted by its members across the Atlantic. The consequent interchange of specimens of members' work, as well as methods and ideas connected with stereoscopic photography, should be of the greatest value to the members. The hon. secretary, Mr. W. Tillott Barlow, The Peaks, Bognor, Sussex, will be pleased to furnish all particulars and receive applications for membership on the Home Circuit: on the American side information can be obtained from the branch hon. secretary, Mr. W. S. Cotton, 5,021, 33rd Avenue S.E., Portland, Ore., U.S.A.

MAGAZINE REFLEX CAMERAS.—In reference to our reply to a querist in our issue of October 24 last, a correspondent, Mr. E. S. Maples, Edgerton, Huddersfield, writes:—"You appear to have overlooked the 'Holborn Reflex,' made some years ago by Houghtons, one of which I possessed ten years ago. It carried twelve quarter-plates in sheaths, had automatic changing, RR or Goerz lens, focussing, but not reversing back, flex shutter behind lens (not focal-plane), speeded 1—1/100 sec. (if I recollect), and was only the weight of a modern focal-plane reflex, certainly not in any way heavy. The 'Flexet' was made by Talbot and Eamer, Liverpool. It was of small size and fitted with either bag-changing magazine, roll holder, or double slides, mirror, behind-lens blind shutter (not focal-plane), 1/10—1/100 sec., rising front, non-reversing back, lens mounted in focussing jacket. Both these were excellent for amateur use where high-speed is not required, the latter particularly being light, small, well-made, reliable, and low in price (£3 10s. plus cost of lens). These cameras are, I believe, no longer made, but could probably be obtained second-hand."

JUBILEE ISSUE OF "NATURE."—Our scientific contemporary in its issue of November 6 last celebrates the completion of fifty years of publication. Sir Norman Lockyer, its founder and for many years its editor, contributes a few "Valedictory Memories," describing

the establishment of the paper in 1869, and is himself the subject of an eloquent appreciation by M. H. Deslandres, Director of the Astrophysical Observatory of Meudon. A photogravure portrait of Sir Norman Lockyer is presented as a supplement, uniform with the portraits of other "scientific worthies" which "Nature" has issued from time to time. The opportunity is taken to publish a series of brief reviews of the progress of various branches of science since the establishment of "Nature," and the issue will be read with very great interest for this series of contributions by eminent scientific men of the day. The branches of chemistry provide the chief subjects for these essays, and have prompted the contributions of Sir Edward Thorpe, Professor Armstrong, Professor H. B. Dixon, Professor J. C. Philip, Sir J. J. Thomson, Sir Ernest Rutherford, Professor Soddy, and Professor J. S. Townsend. Mr. Chapman Jones contributes a brief sketch of progress in photography, and Mr. Emery Walker attempts the same task in the field of photo-mechanical reproduction. These brief papers are appropriately rounded off by one on the promotion of research by Sir Richard Gregory, for many years acting editor of "Nature" and now its editor-in-chief.

Correspondence.

- * * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE ETERNAL QUESTION AND THE P.P.A.

To the Editors.

Gentlemen,—In your last issue Mr. A. W. Woodmansee writes: "The proposal to form a union under the auspices of the P.P.A. will appeal to very few assistants." May I say that these words must have been penned under a misapprehension? The P.P.A. has no intention of "fathering" a union of assistants. The policy of the Association is clearly expressed in the resolution passed by its Council on June 13 last, viz.:—"That this Council of the Professional Photographers' Association, believing it would be to the general advantage of professional photography that assistants should have an association of their own, urge them to form one, and are willing to provide the sum of £10 to a responsible committee towards the initial expense."

It is obvious that the recommendation is that photographic assistants should have an association of their own.—Yours faithfully,
S. H. Fry, Hon. Secretary.

A SIMPLE VARNISH FOR NEGATIVES AND PRINTS.

To the Editors.

Gentlemen,—It has always been advised that all good negatives should be preserved by varnishing them. A cheap and excellent varnish which can be obtained by your readers living in the tropics almost for nothing is to take a bit of gum dammar, say 20 grs. (obtainable from all the Indian shops at a penny an ounce, and known to them as "Arpus" or "Dammar Punai"), and dissolve it in 2 ozs. of motor spirit. Apply the varnish with cotton. If the varnish is not required, it can be removed with the spirit in a few seconds. For bromide prints it might be well to add a little bit of wax and turpentine to the dammar solution. The spirit and the turpentine will evaporate, leaving an invisible varnish on the prints, which will repel water or moisture.—Yours faithfully,

Treasury, Penang, S.S.,
October 6, 1919.

TAX HOOK ANN.

THE ETERNAL QUESTION.

To the Editors.

Gentlemen,—With reference to Mr. Woodmansee's letter in the issue of the 7th inst., his suggestion that the photographic assistants join the National Union of Shop Assistants is certainly good, but I feel sure it will never come to pass, because there is no unity of fellowship in the photographic profession. Take, for instance, one example: I sometimes see announcements which state "No objection to hours." Is that comradeship? If we were in a union they would not dare say that. If they succeed in securing a situation through their "glorious sacrifice," I sincerely

hope they will secure their "tickets" for the next world at the same time. If our profession were indispensable things would be different, but I doubt if the National Union of Shop Assistants would entertain us in their union.—Yours faithfully,
"STILL HOPING."

To the Editors.

Gentlemen,—But for the fact that "Still Hoping" has been only recently demobilised his letter should not have been written. Eighteen months ago the columns of the "Journal" contained much correspondence from assistants, and he should know that it is entirely the fault of assistants if they do not form an association of their own and discuss their grievances together. I think it highly creditable to the P.P.A. that they should have been the first employers' association to recognise the trend of modern industries, and have asked the assistants to form a union which they can treat with. There is no proposal now to form that under the control or influence of the P.P.A., and the fact of the P.P.A. suggesting the formation of this body should make it easy for assistants to meet together without fear of adverse consequences.

The Shop Assistants' Union has for years accepted photographic employees as members, but the conditions of photographic employment are so different from those of the ordinary shop assistant that it would be much better if the photographic ones could form an association of their own. Three-fourths of them are probably "factory hands" in a technical sense and some are at times employees of other trade workers on their own account. Besides that, both on the male and female side, a certain number are continually joining the ranks of those who cater for the public directly. Women's competition exists in other occupations, and though I am certainly not desirous of seeing clever women starting studios in my district, we must all admit that for half the studio work done, given equal technical ability, it would be quite as appropriate for it to be done by women as by men. If the women crowd us out we must try our hands at something else, but I don't think there is much fear of it yet.

The chief difficulty in the way at present is that in the smaller towns there are so few assistants and in the larger they are not acquainted with each other, also the shoe does not pinch all alike. "Still Hoping" says he did not know till he was engaged that there was Sunday duty. That's his own fault.

I would suggest that London should take the lead, and if a few assistants between now and the middle of December would canvass the employees of various studios they might then be able to arrange and advertise a social gathering shortly after Christmas, a portion of the time being occupied with business matters and the remainder devoted to a dance. If this were repeated once a month during the winter it would soon be found whether or not a permanent association could be formed. If it did get formed, then no doubt the £10 cheque offered by the P.P.A. would be forthcoming towards preliminary expenses, but there would have to be a little spade work done first.—Yours truly,

LOOK FORWARD.

PHOTOGRAPHIC GOODS AND THE PROFITEERING ACT.

To the Editors.

Gentlemen,—I was pleased to see in your issue of October 31 that Mr. Robert H. Rice has laid a complaint before a Profiteering Tribunal about the price of bromide postcards, and that the Council of our Association (the P.P.A.) are backing him up.

On September 8 last I wrote to the President of the Board of Trade asking him to "apply the Profiteering Act to photographic glass plates, postcards, paper, and chemicals." At the same time I stated that there was a "combine" or an agreement for the fixing of prices among the "leading manufacturers of photographic plates and papers."

Under date September 13 I received an acknowledgment of my letter. By letter dated October 14 I was informed that the "Complaints Committee" had decided that the "article" complained of is not at present included in the Schedule to the Profiteering Act, 1919." The letter further stated "that immediate steps are being taken to include this in the Schedule, which will be extended in the immediate future."

It would be a good thing if representatives of the P.P.A. and of the Manufacturers' Association could get together, and, if possible, issue to professional photographers and to manufacturers

an agreed statement as to the prices that ought to be charged to the professional for plates, postcards, and paper; for chemicals, also, if possible, but the latter would be more difficult. Manufacturers have had to contend with very serious difficulties. They have survived, have come out on top, and have done very well. The best minds of the times are out for conciliation and for good will. Cannot we have that between the manufacturers and the professionals?

Failing agreement as to what are fair prices, we professionals must fight the manufacturers. So here is an olive branch in one hand, and a sword in the other!

Any action taken by professionals under the Profiteering Act will, I think, be much more effective by all participants (or belligerents!) working together through the P.P.A. Some weeks ago a traveller in our trade said to me: "To hell with the 'combine.'" To that I prayerfully assented.

A. SIMPSON.

3A, New Briggate, Leeds, November 4, 1919.

[In order to render definite the third paragraph in our correspondent's letter, we applied to the Board of Trade, and have been informed that sensitive emulsion-coated plates or papers have not (up to November 8 last) been placed on the schedule of the Profiteering Act, and that therefore it is not competent for a local committee to deal with complaints in respect of the sum charged for these goods. We see, however, in last week's "Board of Trade Journal" that photographic materials are among the goods complaints in regard to which were lodged with the Central Committee appointed under the Act.—Ed. "B.J."]

UNRETURNED PROOFS AND THE PHOTOGRAPHER'S LIABILITY AS TO THE NEGATIVES.

To the Editors.

Gentlemen,—The case relating to unreturned proofs referred to in the "British Journal" of last week raises a point of practical interest to photographers, but the legal principles on which an answer to the question depends are surely so clear that there can be no doubt of the decision which would be arrived at by a Court of Justice.

The question depends on the provisions of the Statute of Limitations, 1623 (21 Jac. I., cap. 16), which enacts that an action on a simple contract (i.e., a contract not made by deed) must be brought within six years. Further, any action on the case generally must be brought within six years from the time that the right of action accrued.

In order to make the matter quite clear, let us suppose a case more in favour of the sitter than the present case. Suppose that the customer had returned the proofs and that the photographer had made default in supplying the prints ordered. In this case, the customer could sue for breach of contract or could rescind the contract and sue for the return of his money. But after six years from the date of the contract all rights of action would be barred under the Statute of Limitations, and the customer could neither sue on the contract nor for the return of his money. The facts of the present case are the same, except that the customer, by failing to return the proofs, put it out of the power of the photographer to perform his contract. It is, therefore, quite clear that any right of action of the customer was barred at the expiration of six years from the date of the contract, and that the present owner of the business is under no liability.

Another question incidentally raised is as to the liability of a photographer for the safe custody of negatives. In the absence of a special contract it seems that a photographer is under no obligation to keep negatives. The usual contract between photographer and customer is that the photographer shall supply a certain number of prints in consideration of receiving a certain sum of money from the customer. As soon as the photographer has supplied the prints his liability under the contract is determined by performance. If the customer afterwards orders further prints he makes an offer of a new contract, which does not become binding on the photographer unless he accepts it. If, therefore, the negatives have been lost or destroyed, the photographer can be under no liability unless he accepts the customer's offer, and, of course, he is under no obligation to do so.

The negative, which is the property of the photographer, is simply an object made by him for the purpose of carrying out his

contract to supply prints, just as a manufacturer might make a mould in order to supply a number of casts ordered from him, or a shoemaker might make a last in order to supply a pair of boots. The customer has no rights whatever in the negative other than the right (arising from his copyright in the photograph) of restraining the photographer from publishing prints made from it.—
Yours, etc.,
SYDNEY C. SPINK, LL.B.

Lochiel, Dyke Road, Hove,

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- H. B.—We know of no agents in this country for the Condensed Chemical Dictionary; our publishers are not supplying it.
- G. H.—You can obtain spare parts and accessories for Goerz cameras from Mr. R. E. Peeling, 4-6, Holborn Circus, London, E.C.
- D. D.—As we understand the Licensing Order it certainly applies to itinerant photographers, since it applies to any retail business which is carried on locally.
- D. W.—We do not know of any firm publishing working drawings. Messrs. Cassell have a book on making photographic apparatus the drawings in which are, we think, about the nearest thing to what you want.
- T. D.—If the registration is being made because the business is not being carried on in the names of the partners, then the office to which you should apply is 39, Russell Square, London, W.C.1. The cost of registration is 5s.
- W. M.—If you have been carrying on a local business in photography for four years past you certainly do not come under the Retail Businesses (Licensing) Order, which applies only to businesses established since February, 1918.
- F. F.—Every photograph taken by a photographer "on his own" becomes automatically copyright, and it has not to be marked "copyright." We suggest that you should read the article on this very subject in the "B.J." of Oct. 31.
- H. B.—If the business is being newly established, and carries on a retail trade locally, you require to obtain a licence under the Retail Businesses (Licensing) Order, the office for which is 15, Athol Crescent, Edinburgh. There is no other formality.
- E. M.—We think from your description that the process is a modification of the true-to-scale method worked out and patented a year or so ago by the firm of B. J. Hall, Great Peter Street, London, S.W. We think if you wrote to them you would find out what you wanted.
- E. P.—Presuming that your friend is a British subject, the photographs which he has taken automatically become copyright in this country without his doing anything at all. You should see the article on this very subject which appeared in the "B.J." of October 31.
- J. D.—Your best plan will be to have two thin curtain poles or even wires, one at the top of the window and one 4 ft. from the ground. Run the curtains on these with rings, in two rows. Have dark sateen or casement cloth curtains at each end and white nainsook ones in the centre.
- N. E.—We have not published instructions for making a print washer and do not know of any book containing them. Most makers of enlargements do not use mechanical washers at all, but simply transfer enlargements from dish to dish of plain water. Worked properly, this is by far the most efficient system of washing.

F. B.—Presuming that the F. and the A.E. are the initials (and the full initials) respectively of your wife and yourself, you do not come under the Business Names Registration Act, but it is necessary that a licence should be obtained for starting a new business, the office for which is 99, Queen's Gate, South Kensington, S.W.7.

A. B.—A common cause is a developer which does not act quickly enough. Most gaslight cards should come up to full depth the moment they are placed in the developer. If they don't the high-lights are very often stained. Your two latter queries would be better answered by the makers of the card, since you do not tell us what brand you are using.

C. E.—We think 1 part of glacial acid to 10 of water will be strong enough to move the distemper. About 2 ozs. of the gelatine powder dissolved in a pint of warm water would be enough to hold the 2 lbs. of whitening. Wet the canvas first, and put on the distemper thinly. An ounce of white sugar will be ample, but it really should not be necessary if you only apply a thin coat.

J. F.—We are afraid there is no remedy for stains on clothes caused by M.Q. developer. The best thing you can try is a little bleaching powder (chloride of lime) made into a thin paste with water and a drop or two of hydrochloric acid added to give the mixture a strong chlorous smell. This may take out the stain, but in nine cases out of ten will take out the colour of the fabric also.

W. A.—1. There is no other system which has any advantage as regards cost of convenience over the condenser lantern. The Parallax is sold in America, but so far as we know has not been very widely used. We should think it is rather costly. 2. An excellent type of printing box was fully described, with drawings, in an article by Mr. W. Marshall in the "B.J." of March 30, 1917. 3. They are probably due either to dirt in the washing water, or in the drying room, or to floating developer dust settling on the plates before development. We can only suggest filtering the tap water, drying negatives in a muslin chamber, and proper cleanliness in making up developer. 4. For fine work, waterproof ink is about the best thing. You can get it from any dealer in process requisites, such as Messrs. John J. Griffin and Sons, Kemble Street, Kingsway, W.C.2.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In a leading article we endeavour to make clear the very confused position in which old photographs stand as regards copyright, owing to the inconsistencies, as regards the definition of "author," between the present (1911) Act and that of 1862, which it supersedes. (P. 674.)

The concluding portion of the notes on the photography of tiled rooms and premises, issued by an American association of tile manufacturers, will be found on page 676. As in the case of the previous series of notes, they emphasise in an excellent way many of the things which require to be kept in mind in the making of satisfactory commercial photographs and lose nothing of their value from the fact that they are written from the standpoint of the user of the photograph.

In his article this week "Practicus" deals with the carbon printing process, outlining in a general way the manipulation necessary in working the double transfer form of it. (P. 675.)

In reply to a question in the House of Commons it was stated that aerial methods of surveying for mapping purposes are at present more expensive and less accurate than those employed by the Ordnance Survey. (P. 685.)

Nearly 138,000 photographs of soldiers' graves have been supplied by the War Office organisation responsible for this work. (P. 685.)

The National Union of Shop Assistants sends us a letter pointing out the position it has taken up in reference to the admission of photographic assistants. (P. 686.)

After having held the office for twenty-nine years, Mr. H. C. Hemmingway is retiring from the secretaryship of the Rotherham Photographic Society. (P. 680.)

Details of construction of anastigmat lenses and of a self-portrait shutter-release figure under patent news. (P. 680.)

A pattern of folder which provides good protection for the photographs and at the same time is of distinctive appearance forms the subject of a paragraph on page 673.

Inadequate contact between negative and printing paper is the cause of defective quality in many prints which are made at the present time. (P. 673.)

We repeat an oft-quoted maxim that photographers should ascertain the cost, not of materials only, but of their own labour, rent, rates, etc., applying to any particular job. (P. 674.)

Stained prints, business agreements, licences for new businesses, and duration of copyright are among the subjects briefly dealt with in "Answers to Correspondents." (P. 687.)

EX CATHEDRA.

A Mounting Hint. We recently handled a number of etchings, which were protected by being placed in folders composed of large sheets of thick cartridge drawing-paper. The prints were attached to the third page by the corners, while an opening cut in the front leaf allowed the whole subject, including the artist's signature, to be seen without risk of damage from handling. In one or two examples, where the edges of the plate paper were already frayed, additional security was given by fastening the front leaf to the back one by means of a thin line of glue down the fore edge. Although primarily designed as a protection, the effect as an artistic entourage was distinctly good, and might well be adopted for any large-sized photographs in monochrome to which it was desired to give an appearance of distinction. One advantage of fastening the edges together is that when displaying the prints from a portfolio there is no risk of damaging them if one be pushed down between the others. Very little skill is necessary to cut the openings, this being easily done by means of a mount-cutter's knife, a steel straight-edge and a sheet of glass. A piece of card can be cut into a templet and a line ruled with a hard pencil or, better, a stylus, to serve as a guide for the knife.

* * *

Unsharp Prints.

Contact printing from small negatives, especially films, is now carried on under conditions which would have horrified many of the old school of printers, who were used to handling negatives made on patent plate-glass, and using "box-form" printing frames with powerful springs. To them the idea of laying a wrinkled film upon a glass bed, putting a piece of stiff bromide paper in contact with it, and lightly pressing a pad upon it to secure contact between them, would have appeared the acme of slovenly work, yet this is what is being done every day by many firms who undertake amateur work. We were struck by the difference in two sets of prints, one being made by the amateur who had produced the negative, and the other by a local chemist, who probably farmed the work out. The former set were quite sharp, but the latter, while good in other respects, were far inferior in this one particular. This is a foolish policy, as it does not encourage the customer to order additional prints, and puts the question of enlargements out of the field. For ordinary portrait work the frames used are often very defective: the little resiliency the springs originally possessed have often long departed, and the backs have warped. With the stout papers now commonly used there is need for far more pressure than when albumenised paper was the only printing medium.

Costing Systems.

In many businesses a careful record is kept of the cost of each job so as to form a basis for quoting for future orders. In the printing trade, in which much machinery and many processes are used, it is quite a difficult matter to do this, and the ingenuity of the whole trade has had to be employed to evolve a reliable system. The photographer may well take a hint to do something in the same direction so that he may avoid taking on jobs which we have described as "paying a shilling for thirteen pence cost." On several occasions we have pointed out that the cost of a finished photograph includes much more than cost of materials, labour, and renewals of apparatus. Time is the commodity which the photographer gives away most freely. On a small outdoor job he will frequently spend as much time in travelling and waiting about as, at bricklayers' or carpenters' wages, would amount to half the sum he receives. Many small photographers work outrageously long hours for a very scanty return. Surely, if they work eighty hours per week, they should be charging out these hours at 1s. 6d. each at least. Then comes rent of business premises, materials, help and profit. Why should a man pay himself less per hour than he would have to pay anyone else to do the same work?

COPYRIGHT IN OLD PHOTOGRAPHS: THE EFFECT OF THE 1911 ACT ON COPYRIGHTS CREATED UNDER THE 1862 ACT.

WHENEVER a piece of legislation is repealed by another, there is bound to be a certain degree of difficulty in deciding what is the position, in the period of the repealing measure, in regard to events which took place under the legislation which has been repealed. The law relating to copyright is an instance of this, and evidently, as some recent questions show, is one which photographers are not always able to settle off-hand to their own satisfaction. Although the 1911 Copyright Act has very greatly simplified and, from the photographer's point of view, improved copyright law, there is still the occasion for doubt as to what is the position of photographs taken before the present Act came into force.

In order to put this matter clearly to others than our correspondents, it should first be pointed out that it is now immaterial, so far as the subsistence of copyright is concerned, or, rather, so far as concerns the photographer's right to take action for infringement, whether the photograph was or was not registered at Stationers' Hall in accordance with the provisions of the previous (1862) Act. Under this former Act copyright was created, just as it is under the present one, by the creation of the work, but it was made a special condition that no action could be taken in respect to infringement which was prior to the registration of the photograph at Stationers' Hall. This disability is removed in the 1911 Act, and, at the same time, the benefit thereby conferred upon photographers extends retrospectively to photographs taken under the 1862 Act.

On the other hand, it requires to be made clear that it does not necessarily follow that a photograph taken under the 1862 Act, whether registered or not, is now the subject of copyright. Copyright may or may not subsist in it. And it is not by any means an easy matter to determine whether it does or not. This difficulty arises from the alteration in the term of copyright which is made by the 1911 Act. In this Act photographs are treated differently from other literary and artistic works, and are granted a fixed term of copyright of fifty years from the time of making the negative. Moreover, the Act is retrospective as regards this question of duration, for

Sect. 24 provides that under the new Act copyright in photographs taken under the old Act shall last for the term for which it would have lasted if the 1911 Act had been in force at the date that the photograph was made if—and it is a big if—any copyright at all subsists in the photograph at the time the present Act came into force.

In order to understand the effect of this position it is necessary to bear in mind the provision of the old Act as regards duration of copyright. This, instead of being a fixed term, was for the life of the author and seven years after his death. Thus, it must be remembered that the 1911 Act does not do anything to restore copyright which has ceased to exist through a period of seven years having elapsed between the death of the author and the coming of the 1911 Act into force. As the 1911 Act came into force on July 1, 1912, it follows that in order for copyright to have been in existence (under the 1862 Act) on that date it is necessary that the author of the photograph should have been alive on July 1, 1905. Even then it does not necessarily follow that copyright exists any longer in the photograph, for in the case of photographs taken in the first few years after 1862 the full term of fifty years, provided by the 1911 Act, may have run its course. In most cases, however, the copyright which, under the 1862 Act, was still in existence on July 1, 1912, is prolonged for a few years by the 1911 Act, and therefore at first sight it seems an easy matter for a photographer to decide what his position is in respect to any studio or other negatives in his position.

Unfortunately, it is not so easy as it seems on account of the fact that the meaning attached to the word "author" of a photograph is very different in the two Acts. In the 1911 Act the "author" of a photograph is arbitrarily defined as "the owner of the negative when the negative is made," and may be an individual or a corporate body. But in judgments of the courts under the Act of 1862 it was held that the "author" of a photograph was the person who actually superintended the arrangement by putting the sitter or members of a group into a position, or selected the view and arranged it in the camera. In other words, the "author" very often was not the master photographer to whom the copyright belonged but his studio or landscape operator. Yet, according to this legal judgment, it was the life of this assistant which determined the duration of copyright. It will thus be seen that in probably 50 per cent. of existing studio or landscape negatives made under the 1862 Act it is impossible for a photographer to discover whether the real "author," according to this judicial ruling, was or was not alive on July 1, 1905. How many photographers through whose employment dozens, if not scores, of assistants have passed can say what has subsequently happened to them! Apparently this is one of the things which was entirely overlooked in drafting the 1911 Act. The difference in the definition of the "author" evidently escaped the notice of the draftsmen of the Act. Yet the Act is plainly made retrospective only as regards this one question of duration of copyright. We cannot recollect that the point has ever been raised in any action for infringement of copyright, probably for the reason that in such a case a photographer conveniently forgets the existence of a subsequently undiscoverable assistant, and no one could reasonably blame him for doing so.

THE AVIAR ANASTIGMAT.—By a mistake last week in the review of the British Anchutz camera the word Aeroplan was mentioned as the name of the lens by Messrs. Taylor, Taylor and Hobson, with which the camera will be fitted. This should have been "Aviar," the new model of which is in preparation for the market by Messrs. Taylor, Taylor and Hobson.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).

Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).
 Miniatures (Sept. 19).
 Printing Portrait Negatives (Sept. 26).
 Wedding Groups (Oct. 3).
 Combination Printing (Oct. 10).
 Flashlight Work (Oct. 17).
 Flashlight Portraiture (Oct. 24).
 The Question of Outfit (Oct. 31).
 Telephoto Lenses for Professional Work (Nov. 7).
 Changing Quarters (Nov. 14).

CARBON PRINTING.

I HAVE had occasion to mention the carbon process of printing several times in this series, and it seems fitting that one article at least should be devoted to practical working instructions. The apparatus and materials required, outside that usually found in a photographer's workroom, are simple and inexpensive. Assuming that there is a sufficiency of printing frames with good strong springs, several porcelain dishes in whole-plate size or larger, and some clean dusters, the following articles must be procured—Carbon tissue in the colours it is intended to use (for a start, sepia and warm black are a good selection), temporary or flexible support, final support—also called double transfer paper—waxing solution, a flat squeegee and rubber cloth, an actinometer, some alum for fixing, and, if the tissue has to be sensitised at home, a little bichromate of potash and an ounce or so of ammonia. All these can be procured for a few shillings; the rise in price since 1914 has only been about 15 per cent. It is usual to start instruction in carbon printing by describing the single transfer process, but as this necessitates the use of reversed negatives I will proceed at once to double-transfer, which is precisely similar in all respects except the final transfer, which is not required in the single-transfer process. There are innumerable dodges and modifications practised by carbon printers, but in this lesson I will assume that there is only one way of working, and that the student will not try experiments until he can produce a decent print.

Carbon "tissue," as the pigmented paper is called, may be purchased either in a sensitive or insensitive state. As the price is the same for either variety, and as most early troubles arise in the process of sensitising and drying the tissue, I advise that it be bought in the sensitive state, in which it will keep good, if stored in a flat calcium tin, for several weeks. If, however, it be decided to sensitise at home, it is a simple matter if carried out in the following way:—A solution is made containing 1 oz. of bichromate of potash in 20 ozs. or 30 ozs. of water. The lesser quantity may be used in summer and the greater in winter, or the strong solution

may be used if the negatives are inclined to be vigorous, and the weak one if they are at all upon the flat side. A few drops of ammonia should be added to the solution, to neutralise any acidity, which would cause the tissue to become rapidly insoluble. The tissue should be immersed in the bichromate, one sheet at the time, and the surface carefully swabbed with cotton-wool to break any bubbles on the surface and to ensure even action. If any portions receive a longer coating by allowing streaks to remain, it is quite possible that these will show in the finished print. The tissue should remain in the solution for three minutes in winter and about one and a-half or two minutes in summer. When ready, the tissue should be lifted out of the bath without draining and squeezed down upon ferrotype plate. As the tissue is practically insensitive while wet, the sensitising may be carried out in daylight and the ferrotype plates carried into a weakly lighted room, where they will dry. This room should be warm and well ventilated, so that drying takes about four hours. Slow drying is liable to produce partial or complete insolubility. Sensitive carbon tissue should be treated with more caution as regards exposure to light than platinum or P.O.P., as once light-action is started it continues, so that a piece of tissue exposed to light for half a minute, which might not show any fog if printed and developed at once, would be quite useless in a week.

Very dense or vigorous negatives are not required for carbon printing, although such negatives yield better prints by this process than by any other; but any fairly bright negative will give good results. Very thin flat "gaslight paper" negatives are useless. Before printing it is necessary to "safe-edge" the negatives. This is done by painting with opaque or black varnish a narrow margin round the edge of the plate on the glass side. The tissue must be the full size of the negative, so that the edges are protected by the safe edge, or there will be danger of the deep shadows of the picture starting to frill up from the edges and ruining the print.

Having filled the frame, we turn our attention to the acti-

nometer. This in its simplest form is a small tin box with a glass lid. Inside the lid is a brownish tint with a small clear hole about $\frac{1}{4}$ in. in diameter, and below this is a disc of P.O.P. We turn the lid until a fresh surface of P.O.P. is under the hole, and simultaneously expose this and the printing frame to the light. If the negative be rather a thin one and free from stain, we expose until the P.O.P. matches the brown tint round it. This we call one tint—it should be sufficient for thin good negatives; for thicker or stained negatives, two, three, four, or even up to eight tints may be needed—that is to say, the P.O.P. is changed and printed to the tint that number of times. With experience it is quite easy to estimate the number of tints needed, and there is sufficient latitude in the development to compensate for a moderate degree of error.

When printed, the tissue may either be developed at once or may be stored in a calcium box until convenient. If prints are left exposed to the air they will continue printing, and under-printed copies may be saved in this way.

Meanwhile the temporary supports should have been waxed and polished. This is done by pouring two or three drops of waxing solution upon the coated side of the support and spreading evenly over with a small pad of new flannelette, taking care to avoid streakiness. When about a dozen have been coated, the first will be ready for polishing with a soft, clean duster, after which the surface should appear smooth and satin-like. The supports should be waxed at least an hour before they are to be used, and will keep in condition for a month. Opals or ground glass supports are waxed in the same way.

A dish is filled with cold water, say at 60° , and a piece of temporary support laid in it face upwards. Above this is floated a piece of exposed tissue face down. The tissue will at first curl with the gelatine surface inwards, but will gradually flatten out, and if left alone would begin to curl the reverse way. But before this begins—that is to say, as soon as the tissue is flat—it must be adjusted upon the support, withdrawn from the dish, and squeegeed down between the rubber cloth and a smooth board or glass plate. If there are

any ridges on the board they will show on the print, as will also uneven or excessive pressure when squeegeeing.

The tissue is now known as "mounted," and must be placed in a blotting book under light pressure for a few minutes, when it will be ready for development. This is effected by immersion in hot water. About 90° Fahr. is a good average temperature. In a minute or two—perhaps longer in the case of tissue which has been kept some days after sensitising—the pigment will begin to ooze out between the two papers. A corner may now be lifted, and if the backing paper comes away freely it is stripped off and thrown away. We have now a smudge of gelatine left on the temporary support, which we place upon a glass or zinc plate and move up and down in the water. If the exposure has been on the short side, the image will develop fully in this way, but most prints require to have the warm water splashed upon them with the right hand while the print on its supporting glass is held in the left. As soon as the highest lights are sufficiently clear, the print is rinsed in cold water and hung up to dry. Hotter water may be used for over-exposure, and in extreme cases a little washing soda may be added. In both cases, however, there is danger of a reticulation of the gelatine in the shadows, and this usually spoils the print.

When quite dry, the print is ready for the final transfer. We do this by soaking a piece of double transfer paper in tepid water until the gelatine surface feels slippery between the thumb and finger. The print is then slipped into the water for a few moments and the gelatine side of the transfer paper brought into contact with the image and squeegeed in the same way as when mounting the exposed tissue, taking care as then to squeegee lightly. The whole is then hung up by one corner till dry, when the print should separate of its own accord from the support, which can be re-waxed and used again and again, so long as the surface is not damaged. The print should be immersed in a 5 per cent. solution of common alum for five minutes, well rinsed, and hung up to dry. This is a bare outline of the operations; next week I will give details which I have omitted to avoid confusion.

PRACTICAL.

SOME SUGGESTIONS ON PHOTOGRAPHS OF TILE WORK.

[We are glad of the opportunity of reprinting through our contemporary, "American Photography," the following notes which form a booklet issued by the Associated Tile Manufacturers of the United States specially in reference to the conditions which require to be observed in making commercially valuable photographs of rooms and places for the floors and walls of which tiles are used. It would seem that the notes have been drawn up for the information of individual tile manufacturers. At any rate, they exhibit such an informed sense of what is required in photographs, not only of these subjects, but of commercial subjects in general, that they deserve the widest publicity which can be given to them among photographers.—EDS., "B. J."]

II.

THE eye is accustomed to perceive three dimensions and their regular diminution as they recede more and more from the eye. This peculiarity of vision must be apparent and seem natural in our photographs. All photographs are rendered in perspective, but, as we shall see, some emphasise or distort perspective. The severe geometrical character of tile work requires especially good perspective.

The perspective of a photograph depends on the focal length and view-angle of the lens, the station point and the level set-up of the camera. Focal length, view-angle, and station point are reciprocal and will be treated together.

Every subject has what might be called its natural viewing distance and viewing height, and a photograph showing the subject as it appears to the naked eye from that point is more pleasing and natural than another of the same subject viewed from a lesser or greater distance or elevation.

To make this clearer, let us assume that a fireplace were to be photographed (fig. 1). In order to take in the entire view of a

5-ft. fireplace comfortably with the naked eye, we would station ourselves about 10 ft. or 12 ft. away (*A*) and look at it from a height of 5 ft. or 6 ft. We do this unconsciously, for the horizontal angle formed by the visual rays between the eye and the extreme left and right ends of the fireplace will then correspond to the natural visual angle of the human eye, somewhere around 25 degrees. This, then, gives us a clue where and how high to set up the camera, provided we have a lens with a similar view-angle (a long-focus lens).

But we may also assume the same fireplace viewed from an easy-chair in front of it into which we have settled down determined to dig through these pages. In this position (*B*) we would not be able to take in the entire face of the mantel without moving the eyes. Moreover, instead of looking down on it from an elevation of 5 ft. or 6 ft., we should see it from a height of, say, 3 ft. Now, we might call this a natural viewing distance also, and feel justified in doing so. But we shall directly see wherein we are mistaken. If we set up our camera equipped with the 25-degree lens at this

point we find that only one-third of the fireplace appears on the focussing screen. Should we be forced to photograph the entire fireplace from this point, we would have to employ a lens with a view-angle of at least 60 degrees. But the minute we do this we lose the very quality of naturalness in the perspective that has been emphasised as highly desirable.

When a small subject is photographed, as a mantel, this short-coming does not affect our picture seriously. But supposing we

Fig. 1.

wish to photograph part of an average room 16 ft. x 24 ft. in size. Figures 2 and 3 plainly show what portion of the room we could expect to reproduce with lenses of different view-angle from a fixed station point. *AA* is the portion included by the natural view-angle of 25 degrees; *BB* that of the ordinary anastigmat. With *CC* we enter into the wide-angle lenses, and *DD* indicates

Fig. 2.

the extensive covering power of the extreme wide-angle. Were this same room only 14 ft. long instead of 24 ft., as shown by the dashed line, we can see that no other than a wide-angle lens could be used to photograph an entire wall.

This brings us to the conclusion that in large-sized rooms we can expect to get very near to natural perspective, and should

Fig. 3.

demand it in our photographs. But we also know that this quality must be sacrificed in photographing small rooms. And so we have drifted from perspective into a consideration of lenses.

Not by any manner of means is it possible to say just what lens to use for the class of work in which we are interested, no matter how much we should like to do so. But it can't be done! Remember, the lens must be chosen with regard to the station point.

The best all-round lens is an anastigmat of the symmetrical

type having a focal length of not less than the dimension of the long side of the plate, which in our case would be 10 ins. As soon as the focal length falls below this dimension, the perspective will become violent. Anastigmats have many advantages: they have great depth, cover a good-sized field, reproduce all objects in the same plane without distortion, give uniform sharpness, and can be used under a great variety of circumstances.

Wide-angle lenses find extensive use in architectural work and render valuable service in crowded quarters. But photographers are apt to use them for all interior work indiscriminately, irrespectively of the available space; and this should be prevented. For, as we have seen, these lenses accentuate the perspective, make a room appear much bigger than it actually is, and picture objects near the camera not only too large, but also disagreeably foreshortened. And in all this work we must be determined to obtain as much naturalness and truth as possible. Any subject should be approached with this clearly in mind. We would rather have a smaller portion of the wall shown in natural perspective any day in preference to a larger section obtained at the expense of naturalness.

Some photographers avoid the use of wide-angles by placing plate-glass or polished metal mirrors—as clear and correct as possible—in place of the camera, and then photograph the picture mirrored in it. Unfortunately, this is practical only where the subjects are of moderate size.

For completeness' sake mention should be made of telephoto lenses. They offer advantages in very large buildings, in churches, etc., when it is impossible to set up the camera close to the object on account of intervening fixtures or pews.

Now, the tile man will have little to do with the selection of the proper lens, and probably cares less. But we have treated this problem in detail, so that he will know, in selecting his subjects, what may be expected and what not. He will then try to avoid jobs that place unnecessary limitations upon the photographer, and this is the real reason why he should familiarise himself with the peculiarities of lenses.

By arrangement, we have here reference to "artistic arrangement by an artistic mind." To begin with, only that portion of the tile work should be selected which gives promise of producing the best picture. Only in rare cases does the view of an entire job make a pleasing picture. Consequently the artistic and appealing side should never be sacrificed for the sake of showing a vast amount of tile.

More or less latitude is left to the photographer in the choice of a station point and the selection of the most suitable part of the tile work under the best possible lighting conditions. If he takes pride in his work he will place his camera in different positions, move it back and forth, up and down, till the image on the focussing screen appeals to his sense of proportion, presents a satisfactory arrangement, shows a relation of parts and forms a tasteful, complete whole. Consciously or unconsciously he applies certain "principles of composition." He moves a chair here, a table there, a vase over there, and so on, and this occasional rearrangement, addition or removal of a chair, a table, a vase, a rug, a flower-stand, a picture, a curtain, and what not, has much to do with the production of a harmonious, enjoyable photograph.

But wait! The heart of the matter lies not in producing an "original" or unusual arrangement. Far from it. Artificial arrangement may rob a picture of much of its convincing powers. And what is balm in one case may be poison in another.

Well, how then shall we arrange? Let Ruskin answer this question: "It is impossible to give you rules that will enable you to compose. If it were possible to compose pictures by rule, Titian and Veronese would be ordinary men." But Ruskin never leaves you thus in the air, for at another point he says: "The principles of composition are mere principles of common sense."

Now, common sense tells us to apply the following principles:—Every picture must have a principal object, the object for which it is taken, and this object must be emphasised in a natural manner. (That's so obvious!) All objects of secondary importance should be arranged or appear in such a way that the eye is led to the principal object. And the principal object should be just a trifle more insistent in crowding itself into the attention of the on-looker than the remainder of incidental objects. This is the principle of Principality.

The next is the principle of Completeness—more common sense. A picture should form a complete whole. The subject of the photograph should be complete in itself. (This does not imply that the whole job must be shown.) Just as the chapters of a book can be complete in themselves, so may a certain portion of tile work be complete in itself. There should be nothing in the picture that leads the eye beyond the edge of the photograph, or sets the mind to wondering what may be beyond, for this would exclude concentration. So, the picture should be self-contained.

The principle of Repetition can generally be applied in pictures of tile work only where rows of windows, columns, chairs, etc., are included and may help in leading the eye to the principal object, or where they themselves are this chief point of interest. Such objects should be photographed in a way that excludes any possibility of monotony. A row of windows exactly opposite the observer and parallel to the picture plane without the helping influence of perspective looks monotonous. This would be reiteration, not repetition as the artist understands the term.

There is also the principle of Radiation, or the convergence of lines of an interior toward the centre of interest, applied in accentuating importance. But all of them are common sense laws, and further enumeration would only entangle and hinder us in freely exercising our individual taste, sense of proportion, and harmony, and similar principles. All are extremely flexible, and some unconsciously applied. Moreover, the constructive principles of each picture are inherent in the picture itself, and the laws and regulations that govern the arrangement of one picture cannot be utilised in the arrangement of another.

The following general hints have been derived from experience. The two halves or sides of a picture should not be congruent. The principal object should appear slightly toward the left or right and below or above the centre of the picture. Dome-shaped ceilings should not be shown without support. The shaft of a column or pillar should not come within the picture unless the capital or base can also be seen. When near the camera, pilasters at the edges of pictures do not close up a picture well.

The principal object of the picture should be in the sharpest focus, at all events, since this will act to emphasise it. But photographers go so far as to subordinate unimportant parts by intentionally holding them out of focus, and here we must object and draw the line between commercial photography—for business' sake—and artistic photographs for art's sake. We are not taking pictures to satisfy our artistic inclinations. While the unimportant portions should be subservient to the principal object, we cannot permit mere suggestive treatment in photographs of tile work. We would very much rather have our prints stamped "inartistic" than show them devoid of definition in "unimportant" sections of tile work to prospective users of tile. For if tile is merely suggested it might appear as if we had to hide some defects; and, besides, to us, tile work is important in every part. Since it is, moreover, impractical to treat the tile work separately and different from adjacent materials, we must leave the matter as stated.

Good anastigmatic lenses can be stopped down to a point of complete focus in every part, and this should be required in all photographs of interiors. Exceptions from this requirement are permissible only in garden scenes, fountains, and other exterior work where the distance may be left in "soft" focus and more the way the eye perceives it.

Without reproduction of joints, tile work cannot be identified as such. Joints constitute what might be termed a necessary nuisance, the reproduction of which is of the utmost importance. A tile wall should plainly show the joints, else it may be mistaken for plaster, marble, or any other smooth material. A photograph of tile work showing deficiency in this respect is therefore worse than useless, and a waste of money.

Faience work presents little difficulty, since the joints are usually wide and consequently not subject to solarisation, to which the disappearance of joints can be laid in general. In walls of white and very dark tile, also in hexagonal vitreous floors of very light and very deep colour, joints have a treacherous habit of disappearing. This phenomenon needs no explanation here, since with exclusive use of non-halo plates for all tile work

no serious difficulty need be feared. No photograph should, however, be accepted unless it plainly shows joints at least in the foreground and middle distance.

The comparative merit of a technical or commercial photograph lies not only with showing line and form in pleasing manner, but to an equal degree with a truthful rendering of colour values. This has nothing to do with photography in natural colours; we still have in mind the ordinary photograph rendered in monochrome. No one wants a blue tile to look white or a yellow one black. But this is exactly what will happen unless we instruct our photographer to take special measures. Truthful colour values can be secured only with special plates and a colour filter fitted to the lens.

The panchromatic plate with correctly fitted filter comes nearest to rendering colour values as the human eye sees them. Orthochromatic plates lack in not rendering the reds. But by far the greater number of tile subjects in colours can be photographed with sufficient accuracy with orthochromatic plates and a ten-times screen. Only where reds and yellows predominate, or are of importance, are the panchromatic plate and its regulation colour screen necessary.

An orthochromatic plate without filter, or an ordinary plate with filter, do not produce the desired effect; the use of the filter would merely lengthen the time of exposure.

In everyday photography finish and texture of a print are matters of individual taste. Some prefer highly polished prints, others think they cannot enjoy a photograph unless it has an absolutely dead surface. With us, this is a matter that has nothing to do with preference. Our choice is bound and tied by practical necessity. We must have a glossy surface to show up all possible detail and permit its reproduction by photo-mechanical printing processes. Even in colour or tone we have a limited choice: a pure black print or a very deep purplish Vandyke brown. Matt surfaced prints on rough textured paper—no matter how artistic that may be—are absolutely unsuitable for reproduction.

We know that this is at variance with the current conception of artistic photography, but we are bound by conditions and cannot show weakness to the pleadings of any photographer. The print must have clear whites and rich shadows, it must have brilliancy, snap. It must be free from the familiar signs of amateur fingers, pinholes, air bubbles, white or black spots, streaks, chemical fogs, cracks and scratches.

Great care must be taken that the corners of the crisp prints are not bent or broken, and never should photographs be rolled or mailed in tubes. Mail them flat, protected on each side with corrugated cardboard.

The best sized photograph for all purposes is 8 ins. by 10 ins. It fits any letter file, it can be mailed in standard sized envelopes, and has pleasing proportions.

Prints should be kept unmounted, since they take less space in files and are easier to handle all around. If liable to be used a great deal, they may be mounted on linen or, better yet, in the following manner: The print is made on single weight paper. A piece of Eastman backing paper is "squeezed" on a ferrotype plate, and the print mounted on this as on cardboard. When mounted in this way the prints have sufficient stiffness to stand up without special supports, yet take up little room in files, and the glossy back remains cleaner than linen or cardboard.

If a picture shows all perpendiculars slanting towards the same side, it is a sure sign that the camera was not set up level, but tilted toward the left or right.

If these lines are converging—but are straight—the camera was tilted either up or down, something that should never be done in architectural work. The focussing screen should always be perfectly perpendicular or parallel to the picture plane.

When any set of straight lines of the job appear in the picture as curves, so that the entire view seems to be projected on a barrel—a fault that is usually accompanied by blurred edges—an unsuitable and very ordinary lens was used for the work. The technical term for this fault is "distortion," and it is characteristic of cheap lenses.

Now and then one will run across a picture that is sharp in the centre, but shows blurred edges, and the corners seem entirely out

of focus. This may be due to various causes, though usually the plate size was too large for the covering capacity of the lens.

Another frequent occurrence is the distortion of the minute squares, hexagons, or rounds of ceramic mosaic into short dashes—the more elongated, the nearer they are to the edges of the print and usually crossing each other, giving a peculiar, unnatural texture to the floor. So it happens that sometimes a tile floor apparently consists of square ceramic, straight joints in front, and herringbone in the background. This phenomenon is known as and results from astigmatism, traceable to the lens. Modern lenses are corrected for this defect and marketed under the name of "anastigmats."

If the entire picture is indistinct or not sharp, either the camera vibrated during exposure or there was some carelessness on the part of the photographer in focussing. Sometimes the foreground is sharp and the background blurred, or *vice versa*; in such instances the diaphragm was not stopped down sufficiently.

The tile dealer cannot, of course, be expected to look after all these details while the exposures are made—they are all part of the photographer's work. They are enumerated here, however, for the purpose of judging the final result and enabling the dealer to point out any shortcoming.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

The Time-Saving Tank.

Now that the busy season is at hand it is well to examine any labour-saving devices with a view to adapting them. To my mind one of the best ways of saving time is by using tanks in place of dishes for development, not necessarily using the Time system, but using tanks for their greater holding capacity.

Let us take a case. The owner of a one-man business is busy operating all day; at perhaps about 9 p.m. he finds himself faced with the task of developing, let us say, 160 half-plates. If he used dishes he would hardly be able to develop more than eight at one time; in which case, allowing 10 minutes' development for each plate, he would take 3½ hours to finish the job. But now suppose he is using tanks—two of them, each taking twenty-five negatives: he can give the same personal attention to each negative, putting those for special treatment into a dish when found necessary, and yet, allowing the same time for development, he will only take half an hour over the job, a saving that is surely worth while.

I may be told that dish development is already obsolete, but I do not think this is so. Especially in middle-class studios it is a common thing for an assistant to have such a job as I have given above, and nothing to do it with except a couple of whole-plate dishes. Surely it is time that this sort of thing was past, for in no industry but ours would such a waste of time and labour be permitted for a moment. An improvement in results may also be expected. It is too much to expect of frail human nature that an assistant will give much "personal attention" to dish developing at midnight, but he will gladly do his best when he knows his hours are not being lengthened by the use of out-of-date apparatus.—
A. G. WILLIS.

The Business Receptionist.

THE receptionist in any studio is usually a busy person; there are always multitudes of small things to be attended to—things it does not do to forget, but which run away with valuable time to an alarming extent. Moreover, no matter how harassed or pressed for time she is, no client can be hurried, nor must any trace of haste appear in her manner—that would be bad business. Yet the receptionist is always expected to do her utmost to increase the turnover of the business by what are sometimes rather loosely termed "sidelines," such, for instance, as the sale of enlargements, miniatures, and coloured work generally; and, indeed, it is to her advantage to do so, as in most studios the receptionist receives a commission, additional to her salary, on such sales.

Photography, as we all know, is supposed to be an artistic business, and perhaps it is for this reason that in so many studios

ordinary business methods, as used in offices, etc., are markedly absent. Yet the skilful use of some of them—or, at any rate, the adapting of them to studio conditions—might do a good deal towards lightening the receptionist's burdens, and giving her more time to devote to the increasing of the photographer's receipts.

Some of these things, by being systematic and methodical, she can do for herself; in others the owner of the studio must help her out, with the necessary apparatus, etc.

In many studios the receptionist does some at least of the coloured work in such spare time as she may have, or else suggests which specimens, if coloured, might be likely sellers.

Now, I suggest that both time and alterations might be saved in this matter by the use of a colouring book, kept by the receptionist for her own and the colourist's use. Whenever a sitter came, of whom in the receptionist's judgment a coloured miniature, etc., might be made, she should note in a few swift glances the general colour of eyes, hair, complexion, clothing, etc., and, directly the client is gone, note these down, with any special details, such as textures of materials, ornaments, etc., in an alphabet book kept by the receptionist for that purpose. This is invaluable, for it is no more difficult in colouring a photograph to make the colouring accurate than to do it by judgment or guesswork, and where the coloured specimen or miniature is bought it will save many alterations, which are bothersome, difficult, and often not quite satisfactory. Many colours of dress materials, etc., photograph of pretty much the same tone, and if the colourist puts in a dress of purple velvet, when it was a green or brown, it involves a considerable waste of time and temper to alter it. Sometimes, too, such a book of colourings will furnish a most useful guide several years later, if, for instance, miniatures or coloured enlargements are desired of some sitter since deceased, where otherwise the colourist must go by guesswork. In noting colourings she will almost unconsciously form a standard of judgment which will assist her much and enable her to be surprisingly accurate in her colouring.

Now, when enlargements and miniatures are submitted to customers in the hope of their purchasing them, a letter must, of course, go with them, which usually the receptionist writes on behalf of the owner of the studio. The busier the season of the year, the more letters of this kind there always are to write, as, for instance, at Christmas. It means orders and money, of course, but it also adds to the work and strain of the receptionist at a time when she can ill spare the time.

Most studios are now equipped with a typewriter, and the fortunate receptionist can jot down notes in shorthand, too, saving much labour. But usually photographers stop at the typewriter, why I don't know. In conjunction with it some form of duplicating apparatus ought to be used. Then, in some slack hour, the receptionist could, at her leisure, draft out a good and telling letter, forcefully put, to go with these approval specimens. This would then be typed and a carefully cut stencil made on the typewriter. Then one of the most careful of the junior assistants could be set to run off fifty or a hundred or more copies of this letter on the duplicating machine, and thus the receptionist would be set up with well-written letters, ready to send, needing only the addition of date, name and address.

Some photographers always circularise their customers at certain times of the year, as before Christmas, Easter, etc., to remind them of the timeliness of photographs as gifts, etc., the pleasure given by family groups at the season when families are most often reunited, and so on. Printed matter is often used, but frequently a better effect might be produced by typewritten matter, duplicated, and with each name and address inserted. It takes a little longer, but it has the more personal note, and that tells in so personal a business as photography. Moreover, if it is planned by the receptionist, it should bear no evidence of this, but seem to come quite straight from the photographer himself. Then, again, once a photograph is submitted on approval some method is needed of keeping check of the time it has been out, and, if necessary, the posting of a second form letter to remind the customer of the specimen. In no case should more than ten days or a fortnight pass before the sending of a second letter, which also can be a duplicate form letter, skilfully written. All this saves the receptionist much worry and writing, and if a commercial "tickler" system is used, and when entering date of sending out on the card the date for the second letter is also noted on its own

card, in advance, at the appointed time this automatic reminder pops up and does its work, and few or no items will ever be overlooked, while much needless strain on the memory is saved and better results attained.

I might here mention another thing. It is often profitable to make a note of casual remarks by customers. If, for instance, a lady remarks how she admires those sepia enlargements, why, note it down, and, when having one made, look it up and submit her one in sepia. It is much more likely to sell. Another will say that he or she does not like enlargements—clearly a case for a miniature; while yet again another will say that he does not like coloured photographs—a clear case for a monochrome enlargement.

It is just such little remarks as these and such notes of them that will prevent unsold specimens lying on hand, when the photographer would much rather have the cheque for them to pay into the bank. In these matters the operator can often greatly help the receptionist by passing on to her any such comments to be noted down, or, better still, doing it for her before it can be forgotten. Usually the receptionist sees all sitters; if not, the operator could easily note for her the details of colouring, etc.

The net result will be an increase to the coffers of the photographer and more commission for the receptionist, with less worry and bother, and, incidentally, well-satisfied customers.—G. E. H. G.

Exhibitions.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

THE thirtieth annual exhibition of the Rotherham Photographic Society was held on the four days, November 12-15, in the Temperance Hall, and drew generous patronage. The war period compelled the promoters to curtail their ambitions by cutting out the open section, and another factor which operated was inability to secure the Drill Hall, a very suitable building, owing to military occupancy. The smaller accommodation this year was the best available, but there was got together in it a really attractive display of pictorial work. A modest attempt to get back to old conditions by inviting outside aid led to a capital entry, and it was encouraging to note the success of members in such good company. The members classed were also encouraging. There was an official opening presided over by Mr. C. H. Moss, J.P., the president, who incidentally mentioned the retirement from the hon. secretaryship of Mr. H. C. Hemmingway (who had held the position for twenty-nine years), and added a few appreciative words. Afternoon tea was served by the ladies' committee. Each evening lantern lectures of a popular type were given, preceded by a short concert. The attendance was exceedingly gratifying, and impressed the council with the urgency of securing a larger room for the next venture. Mr. Bertram Cox, F.R.P.S., Lincoln, judged the principal sections, and Mr. F. A. Tinker, Sheffield, made the awards for members' boards. The awards were as follows:—

OPEN SECTION.

Class A.—Prints (any subject).—Bronze medals: Lionel Wood, Woodbridge, Suffolk, "The Wrestler"; L. J. Steele, Portsmouth, "After the Bath"; M. O. Dell, Walham Green, S.W., "Arens"; Ralph Chislett, Rotherham, "Stone Curlew" (series); and Herbert Felton, Hanwell, W., "Reflections." Certificates: L. J. Steele, Portsmouth, "The Cairn"; T. C. Evans, Clapham, S.W., "A London Lane"; H. C. Hemmingway, Rotherham, "A Famous Stairway"; W. C. Briggs, Rotherham, "Dolly's Ordeal"; Harold Firth, Doncaster, "Reverie"; E. Tinker, Sheffield, "Autumn Woodlands"; and W. H. Reece, Walthamstow, E., "A Winter Evening."

Class B.—Lantern Slides (Monochrome).—Bronze medals: R. Chislett, Rotherham; Herbert Felton, Hanwell, W.; Harry Smith, Birmingham; and Rev. J. V. Haswell, Scissett, Huddersfield. Certificates: Herbert Felton, Hanwell, W.; W. G. Hill, Stockton-on-Tees; Ernest Tinker, Sheffield; T. M. Fowler, Barnsley; and A. S. Pye, Rotherham.

Class C.—Lantern Slides (Colour).—Bronze medals: S. J. Ford, Birmingham, and W. Firth, Rotherham. Certificates: T. Smedley, Sheffield, and Wm. Firth, Rotherham.

MEMBERS' SECTION.

Class D.—Prints (any subject).—Bronze medals: Cecil Robinson, "Portrait"; Hubert Vardey, "Kingfisher"; and E. L. Hardwick, "Kingswood, Roche Abbey." Certificates: Walter C. Briggs, "Larva of Water Beetle"; Thomas Salvin, "Breezy Waves" and "Where the Sluggish Brook."

Class E.—Members' Boards.—Bronze medals: A. D. Robinson and A. S. Pye. Certificates: Miss E. Eskholme, T. Salvin, C. R. Adams, and A. E. Rawson.

Special Medal for Beginners.—R. Beales; certificate, C. R. Adams.

FORTHCOMING EXHIBITIONS.

October 13 to November 29.—Royal Photographic Society.—Secretary, J. McIntosh, 35, Russell Square, W.C.1.

November 20 to 22.—Nottingham and Notts. Photographic Society. Hon. Sec., A. Beeston, 103, Nottingham Road, Nottingham.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Entries close December 1. Sec.: John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, October 27 to November 8.

CINEMATOGRAPHY.—No. 26,892. Cinematograph shutters. J. Crooks.

AERIAL PHOTOGRAPHY.—No. 26,836. Apparatus for photo-restitution of aerial photographs. H. Roussilhe.

STEREOSCOPIC CAMERA.—No. 27,094. Camera for obtaining stereoscopic photographs. R. C. Barron and I. Castle.

COPYING APPARATUS.—No. 27,185. Photographic copying apparatus. A. Buchi.

COLOUR PHOTOGRAPHY.—No. 27,574. Multi-colour screen for natural-colour cinematography and photography and manufacture thereof. J. Camiller and A. Hay.

PHOTOGRAPHIC APPARATUS.—No. 27,543. Photographic accessory and apparatus combined. C. Cox and W. C. Yalland.

DAYLIGHT DEVELOPMENT.—No. 27,612. Daylight roll-film developing box. H. E. J. Culverwell.

PHOTOGRAPHIC SURVEYING.—No. 27,233. Apparatus for photographic surveying. S. M. Dixon.

AERIAL PHOTOGRAPHY.—Nos. 27,413, 27,444, 27,447, 27,448. Method of production of photographic pictures from aircraft. Naamlooze Vennootschap Techn. Maatschappij Aerofoto.

AERIAL PHOTOGRAPHY.—No. 27,403. Aiming practice apparatus for determining machine-gun fire by photographic exposures. Naamlooze Vennootschap Techn. Maatschappij Aerofoto.

COLOUR CINEMATOGRAPHY.—No. 27,108. Apparatus for cinematograph projection in natural colours. A. Plahn.

STRIP-PRINTING MACHINES.—No. 27,559. Photographic strip-printing machines. A. P. Taylor.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ANASTIGMAT LENSES.—No. 153,459 (October 12, 1918). The invention relates to lenses used for photographic purposes, and particularly to those of the type composed of elements separated by air spaces.

An objective of the improved construction consists of two positive and two negative lenses arranged in pairs on either side of the diaphragm. Each pair is composed of a positive lens of relatively

high refraction, and a negative lens having a refractive index equal to, or lower than, that of the positive.

In one pair, the negative lens has a refractive index not greater than that of its adjacent positive, and in the other pair the negative is of lower refraction than the positive lens.

The power of one pair of elements is practically neutral, but may be very slightly positive or negative; and consequently the focal length of the other pair approximates to that of the complete objective.

Generally all the lenses used would be simple, but in particular cases one or more could be composed of two glasses cemented together.

In one form of objective the front pair of elements consists of a plano-convex mounted near to a biconcave lens, and the pair forming the rear portion is composed of a biconvex positive lens mounted very near to a plano-concave negative lens. Both positive lenses are of high refraction. The anterior negative lens is of medium refraction, and the posterior negative lens is of low refraction.

Data for the construction of such an objective are here given. The focal length equals 250 mm. and the working aperture is about one-eighth of the focal length. The description of glass is indicated in the manner adopted by manufacturers of optical glass.

The signs "+" and "-" indicate direction of curvature: "+" being used in the case of a surface having its centre of curvature situated towards front of complete objective; and "-" in the case of a surface whose centre of curvature is situated towards the rear of objective.

Lens.	Glass.	Thickness.	Radii.
Front positive.	N/D 1.611. V = 58.6	12 ^m / _m .	- 76 ^m / _m Plano.
Front negative.	N/D 1.582. V = 41.7	7.5 ^m / _m .	+ 250 ^m / _m - 74 ^m / _m .
Rear negative.	N/D = 1.518. V = 54.	3 ^m / _m .	Plano. - 172 ^m / _m .
Rear positive.	N/D = 1.611. V = 58.6	11 ^m / _m .	- 172 ^m / _m . + 126.5 ^m / _m .

Air space between 1st and 2nd lenses = 7.0^m/_m.

Air space between 3rd and 4th lenses = 3.5^m/_m.

Air space between 2nd and 3rd lenses = 10.5^m/_m.

The claim made in respect to the invention is: An objective, composed of two negative and two positive lenses separated by air spaces, and arranged in pairs in front of and in rear of the diaphragm; the negative lens of one pair being of a refractive index not greater than the adjacent positive lens, and the negative lens of the other pair being of substantially lower refractive index than that of the adjacent positive lens, and also lower than that of the other negative; such objective having one of the mentioned constituent pairs with negative, or not appreciable positive, power, and at least one of its air spaces bounded on one side by a plane surface.—Albert Arthur Smith, 1, Ashgrove Road, Bromley, Kent.

SELF-PORTRAIT SHUTTER-RELEASES.—No. 133,238 (May 22, 1919)

The invention relates to shutter-release mechanism for photographic cameras of the kind in which a clockwork mechanism in a small casing attached to a camera automatically actuates the usual shutter-release device after a given interval of time, indicated by a hand moving over a dial, sufficient to enable the operator to leave the camera and, for instance, take up a position in the group or view being photographed.

The invention consists in a modification of an ordinary watch movement to provide a device of the above described type, the principal features of which consist of a sliding rod to operate the shutter-release, which rod is protruded by a pin on a rotating wheel, and a pivoted detent device for holding and releasing such wheel.

In the drawings *a* is the lens casing of a camera and *b* is the finger-release of the shutter thereof.

On the front of the camera in such proximity to the finger release *b* as to displace the same on complete protrusion of a rod *h* is mounted the contrivance *c* which forms the subject of the invention.

The contrivance is constructed by modifying an ordinary small keyless watch, as follows:—

The escapement is removed, leaving, however, the escapement

train, which will exert a sufficient delaying action on the unwinding of the main spring.

The motion work, consisting of the cannon pinion, minute wheel, minute wheel pinion, and hour wheel, and the hour and minute hands are also removed.

Also for the usual dial, a dial bearing the numerals one to twenty is substituted (see fig. 1).

Fig. 1.

The barrel wheel, as usual, is rotated by the winding stem *d*, winding the main spring, which rotates the barrel.

A spur wheel *e* is secured on the barrel on the dial side of the watch case. This wheel *e* gears with a spur wheel *f* mounted free on the centre arbour of the watch. The wheel *f* has an outstanding pin or stud *g* (see figs. 2 and 4), at such radial distance from the centre of the wheel *f* as to encounter the inner end of and thrust outwards a sliding rod *h*, on rotation of the wheel *f*. This rod *h* is the device which on being thus completely thrust outwards angularly displaces the finger-release *b* and releases the shutter of the camera.

On further rotation of the wheel *f*, the pin *g* thereon escapes past the inner end of the outwardly thrust rod *h*, which latter is thereupon thrust inwards by the finger-release *b* on resuming its

Fig. 4.

Fig. 2.

Fig. 3.

initial angular position under the influence of its spring.

After escaping past the end of the rod *h*, the pin *g* on the wheel *f* encounters the inner end of a lever *i*, pivoted at *i*², the outer end of which protrudes from the watch case, and the wheel *f* is arrested.

Slots for the protrusion of the sliding rod *h* and the lever *i* are provided by notches formed in the inner face of the bezel *j* of the converted watch *c*.

As may be seen from figs. 2 and 3, the slot for the protrusion of the lever *i* is lined on the side and end adjacent to the watch case and to the winding stem *d* respectively, with a strip of resilient material *k* such as rubber, which acts as a spring tending constantly to force the outer end of the lever *i* in directions away from the case and away from the stem *d* respectively. The result of this pressure by the resilient pad *k* is that the inner end of the lever *i* tends always to press towards the plane of the wheel *f* and also move angularly towards the centre thereof.

The inner end of the lever *i* is provided with a finger *i'*, which, when the lever *i* is displaced angularly in a direction away from the centre of the wheel *f*, snaps into the intervals between the teeth thereof, by virtue of the inward tendency engendered in the inner end of the lever *i* by the outward pressure of the resilient pad *k*.

When the wheel *f* is in the position at which it is arrested by contact of its pin *g* with the end of the lever *i*, a hand *l* connected to the wheel *f* is situated over the numeral 20 on a dial *m*. This is in the initial position.

On pressing the lever *i* so that its inner end frees the stud *g* to pass beneath the same, the wheel *f* and the hand *l* commence rotating, the hand moving over the dial *m* in the inverse direction to the sequence of the numerals. When the hand has arrived at the numeral corresponding to the duration of the desired interval to elapse between release of the mechanism and the release of the shutter, the lever *i* is moved angularly so that its finger *i'* enters in the teeth of the wheel *f* and arrests the latter.

When all is ready, the outer end of the lever *i* is pressed towards the watch case, lifting the finger *i'* out of engagement with the teeth of the wheel *f*, and the yielding pad *k* forces the inner end of the lever *i* angularly towards the centre of the wheel *f* where it is in the path of the pin *g*. The mechanism starts, and during the interval before the pin *g*, after encountering the end of the sliding rod *h*, thrusts such rod *h* completely outwards, the operator can leave the camera and assume his desired position in the group being photographed or elsewhere.

The contrivance may be used for actuating the finger-release to close the shutter previously opened by a bulb or the like release to effect a time exposure. Thus the operator need not remain in proximity to the camera when taking photographs by time exposures, and, what is of greater importance, is relieved of the necessity of timing the exposure, such being done automatically by the duly set contrivance.—George Edwards, 120, Victoria Road, Queen's Park, London, N.W.6.

COLOURING PHOTOGRAPHS.—No. 130,896 (January 29, 1919). The invention has for its object to produce, by the use of oil-paints, a coloured picture which has the finished artistic appearance of a water-colour drawing, and which can be produced in a very short space of time.

The print to be treated is first coated with a suitable transparent preparation to form a ground for the oil-paints, preferably a mixture of one part xylonite in solution, two parts mastic varnish, and two parts pale drying oil, the parts being by volume.

A very small quantity of this mixture is used. For example, with a full-sized photographic plate six drops of the mixture would be sufficient, applied with a clean linen rag to the plate and spread evenly over the surface, leaving a thin film for working on.

If the print is an engraving or the like it is given a preliminary coating of xylonite in solution, which is allowed to dry before the application of the mixture above stated.

While the mixture is still wet the colours are applied to the print by means of oil-paints used very sparingly as stains, and not thinned in any manner, as the grounding affords sufficient thinning.

The picture is then allowed to dry in a room, or other place free from dust, at a temperature of approximately 70 deg. F., and is kept at this temperature for at least forty-eight hours, so that it is no longer sticky to the outer side of the finger.

A dressing is then applied to the surface consisting of powdered silica, which is dusted over it and rubbed on lightly until all trace of the gloss produced by the oil-paints is removed, leaving a dull matt surface, with the picture unaffected by the rubbing, and having the appearance of a water-colour drawing.

The quantity of powdered silica required for a full-sized photographic plate would be approximately 16 grs.

The silica dressing may be applied with the fingers in a circular motion completely over the whole surface, and continued until all appearance of oiliness has disappeared, after which the surplus silica powder may be removed with a broad camel-hair brush, and the picture wiped with a clean soft cloth.

When completed, it will be found that the finished print has the soft artistic effect of water-colour work, but it has the advantages of oil-colour painting—i.e., it is fast in colour, durable, and is proof against air, water and oil.—John MacDougall, 16, Claremont

Square, London, N.1, and Samuel Thurley Thomas James, 8, Warwick Court, Gray's Inn, London, W.C.2.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Determining the Focal Length of Hand-Camera Lenses.

HARDLY a month passes (writes Ralph E. Bail in "Photo Era") but some new method of determining the focal lengths of lenses appears in one or another of the photographic magazines. But so many of them require the use of double-extension bellows or focussing backs that the undermentioned method may be of interest, especially to users of hand cameras.

Place a mark on the side of the camera in such a position that it lies in the same plane as the plate or film. Then, after racking out the bellows nearly as far as it will go, focus sharply on some flat object of such a size that its image on the focussing-screen will be 1 in. or so in length. In case a roll-film camera is used, the focussing may be done by stretching a piece of white paper across the rolls in the back to serve as a screen. Now measure the length of the object, the length of the image, and the distance between the object and image (this last measurement being made from the object to the mark on the side of the camera). The focal length of the lens used is then calculated from the equation

$$F = \frac{D \times O \times I}{(O + I)^2}$$

in which *F* represents the focal length of the lens, *O* the length of the object, *I* that of the image, and *D* the distance between object and image.

For a simple illustration: suppose the lens to be focussed upon a 12-in. rule, and, on measuring, the image is found to be 1 in. in length and the distance from the rule to the image 84.5 ins. Then the focal length of the lens would be $\frac{84.5 \times 12 \times 1}{(12 + 1)^2} = \frac{1014}{169}$ or 6 in.

New Books.

DESIGN IN PICTURE-MAKING BY PHOTOGRAPHY.—A little monograph by John Wallace Gillies on "The Significance of Design in Picture-making by Photography" has just been issued as No. 176 of "The Photo-Miniature" (New York: Tennant and Ward, 103, Park Avenue, 35 cents. London: Houghtons, Limited, 88-89, High Holborn, W.C., 1s. 6d.). The little book will doubtless draw the attention of photographers who have no sense of picture-planning to some of the principles which ensure pictorial attractiveness. But whether its author will carry that enlightened conviction which begets the happy assurance of an artist who knows his work is rather to be doubted. Mr. Gillies scarcely has enough to say about the principles he touches upon. He skims the surface and flies on merrily without so much as wetting his wings.

To explain the elusive things that go to make up art-feeling is intensely difficult. Still, it can be done, and perhaps the author of this brochure has achieved it as nearly as most, and better than many, who have set themselves to turn photographers into artists. But the little book attempts far more than its limits can compass. From this point of view, it is an advantage that the author restricts his theme almost entirely to design, which he calls pattern. Feeling he dismisses as something which "is there, or

is not, as the man has it, or has not; and it is for each one within himself to seek out and put that quality into his work." And that is all the reader gets about feeling, as far as its acquirement is concerned.

One of the best passages in the essay is that in which the photographer is assured that the sense of design will come into play intuitively if it is trained and cultivated; "then the placing and spacing of the picture on the ground glass is a matter of unconscious effort."

There are eight pages of illustrations, comprising photographic views, and versions by their side in pencil. These drawings are too far a repetition of the photographs to make much impression on the reader, and their completeness simply amounts to an alternative rendering of the same scenes. They would have had more instructive value in the form of diagrams. Print No. 3, a view of one of the great bridges over the East River at New York City, is an excellent picture, but, to our minds, its impressiveness is due to something quite apart from its design. The overwhelming height and length of the structure, and the sense of the distance covered in the span, are obviously the leading points of the picture. But they are due to linear and aerial perspective alone. The accompanying drawing misses all this, but gives the lines, which demonstrate that feeling or sentiment rather than "pattern" makes a fine picture of the photograph. Mr. Gillies says: "I think a more careful drawing of the subject would be preferable to the photograph in the matter of pictorial interpretation": an opinion to which we cannot subscribe.

The author has found, with many another photographer, that pattern seems to be more easily found in pointing the camera downward, "or using the skyline high in the picture space, as may be observed in the works of those pictorialists whose pictures show a keen appreciation of the interest of design." This is a practice more honoured in the breach than in the observance. It points to the lack of true pictorial insight, which leads people to look about for bridges and cranes and other ponderous structures, whose unrelenting lines they make into gawky compositions instead of discerning the less obvious masses of a complete scene, near and far alike, and welding them unaggressively in one harmonious scheme.

We can, however, recommend the little book as something to set the beginner thinking. F. C. T.

New Apparatus, &c.

Accessories for the Vest Pocket Kodak. Made by M. P. Tiranty, 103, Rue Lafayette, Paris.

THE great convenience and efficiency of the vest-pocket Kodak have not unnaturally been the motives which have prompted M. Tiranty to extend its usefulness still further by placing upon the market a little accessory, which allows of plates being exposed in the camera without interfering with the independent use of roll-film. This little apparatus, to which the name "Adapteplaque B.S." is given, consists of an additional back frame, which is applied to the rear portion of the vest-pocket Kodak, and is held

in place by a stout wire loop, which is passed over the extended front of the camera. It is understood that before placing the adapter frame in position the ordinary film-enclosing back of the vest-pocket Kodak is removed, and that the Kodak is, of course, employed uncharged with film. The plate adapter carries a single

metal plate-holder for plates of 45 by 60 mm. size. The whole attachment is most simply used, and will no doubt contribute to the further popularity of the Kodak V.P. in the way of allowing of it being employed for ultra-rapid plates and for Autochrome plates. For the latter, M. Tiranty supplies a special pattern of dark-slide at prices from 3 to 5 frs. The price of the adapter for use with ordinary plates, and including three single metal plate-holders, is 25 frs.

A further very novel accessory for the vest-pocket Kodak is a case of light leather-covered metal provided with a hinged leather flap and leather carrying strap. The little Kodak is carried in this case, and when required for use the front portion of the case is turned downwards into the horizontal

position after the manner of the baseboard of a folding camera. The Kodak is thus held in position for exposures in the hand, or may be readily attached to a tripod by means of the stout metal bush, which is provided in the hinged front of the case. The little accessory is most ingeniously contrived, and is opened for use within a few seconds. It is supplied at the price of 25 frs.

CATALOGUES AND TRADE NOTICES.

MESSRS. GRIFFIN send us a four-page circular of their current introductions, including metal and amido developers, their inverted gas lamp for enlargers, and Christmas greeting mounts for the forthcoming season.

THE ADHERENT TISSUE COMPANY, 117, Fore Street, Upper Edmonton, London, N.18, have just issued a price-list of their dry-mounting tissue, presses, and accessories for the dry-mounting process. The list contains a table of temperatures recommended for the mounting of various descriptions of print with "Adherent" tissue.

CARBINE AND MAXIM CAMERAS.—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.4, have just issued a circular of revised prices of the Carbine and Maxim roll-film cameras. The former are issued in several models both in quarter-plate and postcard size, and Messrs. Butcher list a large variety of anastigmat lenses which can be fitted.

BRODRICK SPECIALTIES.—Messrs. F. Brodrick, Limited, 50, High Street, Charing Cross Road, London, W.C.2, send us a sixteen-page price-list of their specialties in apparatus for professional photographers. Among these are the drying cabinet and developing tanks which we noticed in these columns some months ago. Other apparatus which is here newly announced is a cascade washing-table for prints in quantity, made according to an admirable design, and a combined hand printing and developing machine for four persons and a total output of 4,000 prints per day. All those engaged in the production of prints on a large scale will find this a list which describes thoroughly workmanlike appliances.

FRIDAY, NOVEMBER 28.

Royal Photographic Society. "How I Make my Bromoil Prints." G. B. Clifton.

CROYDON CAMERA CLUB.

If an expression of innocence be deemed to be an index to a character without guile, Mr. G. Bellamy Clifton, F.R.P.S., provides the proverbial exception so far as relates to his photographic enterprises. Admitted that he occasionally accomplishes most excellent "straight" photography, possibly owing to some crooked influence seizing the opportunity when the patron saint of all arch-fakers has adjourned round the corner to freshen inspiration, yet Mr. Clifton evidently feels happiest when advancing pictorialism by the introduction into Bromoils of deliberately drawn-in figures, or other accessories, as an important part of the composition. Realising that "he who excuses himself accuses himself," he offers no semblance of an apology for these buccaneering expeditions over the peaceful native soil of the camera, but, on the contrary, stoutly maintains that everything and anything is justifiable which tends to advance the expansive policy he has at heart.

Mr. Clifton's visit to Croydon last week with "Bromoil Printing" as his subject was fortunate in being early in the session, as a large number of new members have recently joined, many with but the vaguest notions regarding the process and its potentialities in the hands of a daring draughtsman.

Without going into details of a familiar process, several points raised by Mr. Clifton are of interest, particularly an allusion to an attempt now being made on scientific lines to standardise it. Bromoil, of all processes, he said, was the most temperamental; it could not be taught in the ordinary sense of the word, and every worker would have to find his own salvation. For instance, pigments and bromide papers working well in some hands might absolutely refuse to accede to the wishes of others. Contrary to usual ideas, he preferred to start with a flat and weak bromide print, and at a recent demonstration before a London society he was told that his procedure was wrong from start to finish, which encouraged him rather than otherwise.

He recommended a weak amidol developer, development being continued until all action ceases. He never heated any solution, but used all baths at the normal temperature of the room. "Williams'" bleacher and "Rawlings'" pigment (as supplied by Griffin's), with "Roberson's" medium, worked well in his hands, as did Ilford "Bromono" and "ordinary rough." When ordering, it should be distinctly stated that these bromide papers are required for Bromoil. All "non-stress" bromide papers were to be avoided.

Mr. Clifton then proceeded to give a practical demonstration, terminating it by pigmenting a bleached and fixed bromide print. Now the Croydon atmosphere is not flat or weak, the bromide print was, and apparently out of tune with its surroundings, for the picture began to appear as a negative. Grimly the lecturer's expression set, and a contest began, eventually resulting in a complete defeat of the entrenched picture, only a few shell-holes being finally left as evidence of the conflict. He stated in pre-war days bromide papers never behaved in this way.

In the discussion Mr. R. Dodd said the chemistry of Bromoil was very difficult. Personally, he believed that until a synthetic medium replaced gelatine regularity of results could never be hoped for, though a fair percentage of successes was always possible. Mr. R. E. Crowther, who had been investigating on scientific lines the most suitable type of negative, had stated that a very thin one was the best. "I got the very worst results from that type," here observed Mr. Clifton, smilingly. Mr. A. F. Catherine being possessed of a shaving brush too small for his massive countenance, had given Bromoil a fair trial, but was sadly disappointed with the process. Others spoke, all agreeing to disagree. A most hearty vote of thanks was accorded Mr. Clifton for a demonstration followed with keen interest.

During the interval a short discussion arose on the affiliation scheme for sending a loan collection of slides to Holland. The idea was not enthusiastically received. Noticing this, Mr. J. M. Sellors said he mentioned the matter, being bound so to do, but during the war, when he was at Falmouth, Dutch vessels used to put in, and their crews scoured the town for bacon. Consequently the inhabitants often went short. This recital put the lid on the scheme so far as Croydon was concerned, all agreeing that the appropriation of bacon to Dutch use, which might otherwise have found haven in the distinguished tummy of the honorary secretary, was nothing less than an outrage.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY.—In addition to the usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, the directors have declared an extra dividend of 7½ per cent. upon the common stock—all payable on January 2, 1920, to stockholders of record on November 29, 1919.

LEGAL NOTICE.—Notice is given of the dissolution of the partnership between Louis Myers and Marley Denwood, carrying on business as photographers at Stanley Street, Bury, Lancashire, under the style of "Romney's Studios." All debts due to and owing by the late firm will be received and paid by Louis Myers.

NEW COMPANIES.

BRITISH METAL PRINTING CO., LTD.—This private company was registered on November 10 with a capital of £10,000 in £1 shares (6,000 7½ per cent. cumulative preference). Objects: To carry on the business of metal printers, printers, lithographers, photographic printers, engravers, die sinkers, etc. The subscribers (each with one ordinary share) are: W. Rigby, 8, Newhall Road, Jericho, Bury, sheet metal worker; T. Rigby, 279, Rochdale Road, Bury, sheet metal worker; A. Rigby, 3, Bradford Terrace, Bury, sheet metal worker; W. Brown, 8, New Fields, Birtle, metal printer. The first directors are: W. Rigby, T. Rigby, A. Rigby, and W. Brown. Qualification, £150. Registered office: Britannia Works, Ormond Street, Bury.

News and Notes.

SUCCESSFUL STUDENTS.—At the last examination in photography held by the City and Guilds of London Institute two of the prizes and medals offered by the Salters' Company were awarded to Mr. R. P. Stewart and Mr. G. Beale, both of whom were students of Mr. Edgar Senior at the Chelsea Polytechnic.

PHOTOGRAPHS OF SOLDIERS' GRAVES.—Mr. Churchill recently stated in a reply to a question in the House of Commons that the total number of photographs of soldiers' graves supplied up to date for all theatres of war is 137,877, of which 62,875 have been supplied since the Armistice. There are 31,632 requests still outstanding.

AERIAL PHOTOGRAPHIC SURVEYING.—In the House of Commons on November 10, Lieut.-Colonel Moore-Brabazon asked the Parliamentary Secretary to the Board of Agriculture what steps, if any, have been taken to utilise the experience obtained during the war in connection with aerial photography for mapping purposes towards assisting the Ordnance Survey work in this country, having regard to the fact that many maps are now out of date?

Sir A. Boscawen: The value of aerial photography for the purpose of map-making in the theatre of war is fully appreciated by the Ordnance Survey, and its application to peace surveys is being carefully studied, but at present the process is generally more expensive than normal methods and less accurate. The Ordnance Survey has full information on the subject, and is in touch with those who carried out air surveys on the Western Front and elsewhere. Some of these officers are now on the Ordnance Survey staff.

ROYAL SOCIETY OF ARTS.—Among the Cantor lectures to be delivered at the Royal Society of Arts after Christmas is a series of three on "Aircraft Photography in War and Peace," by Capt. H. Hamshaw Thomas, M.B.E., M.A., of Downing College, Cambridge, and formerly of the Royal Air Force. Photographers will also note with interest a paper to be read, also after Christmas, by Sir Cecil Hertelet, formerly H.M. Consul-General for Belgium and past-President of the Photographic Convention, on "The Ruin and Restoration of Belgium."

RECOVERING SILVER FROM FIXING BATHS.—According to "Abel's Weekly," Mr. Ackerman, chief of the photographic staff of the Caxton Company, of Cleveland, has invented a device for obtaining the silver from hypo baths. It consists of a combination of metals, which, when dipped into the hypo bath, set up a chemical action which precipitates the silver, which collects itself on the wooden frame holding the metal. The device is placed in the bath and left there indefinitely, working while plates are fixed. When enough silver has been precipitated it is scraped off. Mr. Ackerman has had great success with the process himself, and expects to market the device. Very little silver is left in the solution when it is ready to throw away. Another advantage is that the hypo bath with the device set in will last at least a third longer than without the silver remover.

NAVY SERVICE PHOTOGRAPHERS.—With a view to placing the photographic work of the Navy on a permanent footing, it has been decided to institute the non-substantive ratings of photographers, first and second class. Both the seaman branch and marines will be eligible. Candidates must have had previous experience in photography, and must hold no other higher non-substantive rating than gunlayer, second class. They must be recommended by their commanding officers as competent photographers, and particulars must be given of their previous photographic experience, especially in Fleet work, such as triangulation of fall of shot. The non-substantive pay attached to the new branch will be:—First class 1s., second class 6d. per day. Ratings previously employed on Fleet photographic work, and recommended for the new branch, who are not seamen or marines, may, if selected, be allowed to transfer to the rank of private, R.M.L.I. Six photographers will be selected immediately, and will be drafted to H.M.S. "Snapdragon" for service with the Atlantic Fleet. The requirements of photographic personnel in future, at

home and abroad, are, however, under consideration, and further orders will be issued when these are decided, together with regulations governing the qualifications for first and second class rates. Ratings eligible for, and desirous of joining, the photographic branch should apply to their commanding officers. Recommendations should reach the Admiralty at the earliest possible date, and for the present are limited to ratings serving in home waters and the Mediterranean.

PERMANENCE OF KALLITYPE PRINTS.—Mr. David Bachrach writes to "Abel's Weekly" on this subject:—During my over fifty years' experience as a photographer I have handled and studied almost every kind of photographic print except gum prints, and have made the subject of permanence a study. The weakest of all photographic prints are the P.O.P. gelatine prints, and next to them are the old salted and silvered paper prints *not* toned with gold. They are more permanent when thoroughly toned with gold, fixed in fresh hypo, and well washed.

The Kallitype print is of about the same permanence as the old plain paper prints *not* toned. A developed print, made on modern developing papers, is the most permanent of any silver image, as the metal is present in large quantity and more like the pure metallic silver of the old collodion process in making negatives. But they must be carefully manipulated to be permanent.

Those prints can be made almost as unchangeable as platinum prints, if thoroughly fixed, by toning them in the sulphide method, either in connection with a solution of hyposulphite of sodium or by the more direct method. Sulphide of silver is the most unchangeable of all silver products, and is not affected by the atmosphere. I have given these things most careful tests, years ago.

Now if the Kallitype prints can be made by some modification that will allow them to be toned by the sulphide process, they can be made about as permanent as the developed prints. I have no time or disposition to try the experiment, and I will leave that to the younger men to do.

Correspondence.

PHOTOGRAPHS OF THE NUDE AT THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the Editors.

Gentlemen,—Your readers may be interested in an anonymous letter which I have received. Probably the writer has been brought up in a family where it was the custom to drape the pianoforte and table legs. His extreme sensibilities, however, did not prevent him from defrauding the Inland Revenue of a penny. This he accomplished by enclosing his written communication in a page of printed matter and that again in an open envelope bearing a halfpenny stamp.—Yours faithfully,

J. McINTOSH, Secretary.

The letter is as follows:—

"Dear Sir,—I much enjoyed the Exhibition which you were kind enough to allow the public to see—with the exception of 1 or 2 pictures containing *nude females* from life. Those I think were too immodest and indecent for words, and most ladies hurried from them and most men who had brought ladies with them were sorry they had done so.

"If there be such a thing as *modesty* in the world, such pictures as those OUTRAGE it.—Yours faithfully,

"AN ENGLISHMAN."

"The Secretary,
"Photo Exhibition,
"Russell Square,"

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—There is something pathetically humorous about the letters on the "Eternal Question." Do the writers expect that a union for photographic assistants can be established by someone without the help of those interested? Now, if there is any desire to establish such a union, why do not some assistants call meetings in the large cities and towns, such as London, Glasgow, Manchester, Liverpool, Leeds, etc., etc.? Earnest men could easily hire small rooms and call meetings; or such meetings could be called to tea rooms or restaurants. Then, if it is possible to cut the cackle about grievances and get to business, a union could be started, and, once started, would grow, like the P.P.A. and other photographic societies. The P.P.A. has voted money towards the formation of a union, but no doubt looks to assistants setting the ball rolling. A union of photographic assistants could interest itself with the purely trade side, and also imitate the scores of technical societies in giving mutual help to amateur photographers, a point upon which many assistants would benefit greatly.—Yours faithfully,

Glasgow, November 16.

PRACTICAL.

To the Editors.

Gentlemen,—I have followed with close attention the correspondence which has recently appeared in the columns of your journal, and would like to draw the attention of "Still Hoping," "Looking Forward," and also of Mr. Woodmansee, to the existence of a special photographic trade section which was formed under the auspices of the N.A.U.S.A.W. and C in February of this year. It has absorbed the energies of several who have been acquainted with various unsuccessful attempts made in the past to establish an association of photographic assistants. Furthermore, it has secured recognition from a large number of employers, and has been invited by the Ministry of Labour to co-operate in the establishment of an Interim Reconstruction Council for the trade.

Its machinery has been adapted to cater for the professional, distributive, and clerical branches of the trade. The membership already runs into four figures, and it has secured an agreement of minimum wage rates and working conditions with at least nine of the most important firms. This agreement covers, amongst others, the assistants and clerical staff of Messrs. Kodak, Ltd., of Kingsway and depots.

Studio workers of the Army and Navy and other retail stores, works chemists, enlargers and other technical and professional operatives and assistants have taken up membership.

May I appeal to your correspondents and all others interested to communicate with me at the address stated? The non-indispensable character of the profession, referred to by "Still Hoping," need no longer be a barrier to the establishment of improved conditions. The Shop Assistants' Union has been in existence for over thirty years, and possesses a worthy record of constitutional but energetic activities. More than any other society it has been instrumental in obliging the Government to introduce a forty-eight hour working week Bill. Its most recent triumph in this connection was the securing of an extension of the Bill's proposals so as to include managers and assistants in responsible posts generally. This was the result of a consultation between Sir Robert Horne and Mr. John Turner, the Union's general secretary, with other T.U. officials.

Let all assistants in the photographic profession sink prejudice and link themselves up with a responsible and experienced trade union through the medium of a trade section established for and controlled by trade workers only.—Yours faithfully,

HARRY G. WARD, Section Secretary.

Dilke House, Malet Street, London, W.C.2.

MOUNTING BLOCKS TO POINT EMS.

To the Editors.

Gentlemen,—Your remarks *re* mounting of letterpress blocks to inch measurements induces me to say a few words on the subject, as I am sure it is high time that labour-saving improvements should be attempted there.

Every process engraver and electrotyper would frown with indig-

nation if they were charged with being incapable of mounting blocks *type-high*.

Now that the American point system has become indispensable to the jobbing printer he is more anxious than ever that the time-killing method of block-mounting as practised to-day shall be improved and the point system applied to economise time in justifying them to measure. Immediately the printer suggests this he is told "it cannot be done; wood is not reliable owing to shrinking" (he forgets it shrinks one way only), "that it is the custom to mount to inch measurements," etc., etc. These excuses are not trotted out when objection is made to a block not being *type-high*. This fault is tackled at once, and *remedied*.

From an experience of thirty years I can safely say it is as simple to mount a block to ems and ens as it is to make it *type-high*, or as simple as mounting to inch measurements. The average compositor will make any block given him to even ems or ens with the aid of a hack saw, file, and sandpaper. Since your remarks on this subject in the "B.J." only one block has appeared which presents any difficulty in carrying this system out, and that is in Illingworth's advt. (as page iv., September 19, 1919), where the brass rule joins up to the edge of the block. Even this can be overcome by using an electro and grooving the edge of the plate to allow the nails to be driven into the wood.

This would allow brass rule to join up flush on any of the four sides (see below for em measures in designing).

I first saw this method in an electro made in Germany, where there were no open spaces in the design to drive a rivet. This block was for use in fancy jobbing with rules and panels, and was quite accurate enough, and has been in use for years.

After spending several years at a school of technology and discussing the subject with students engaged in the process and electrotyping businesses, I am convinced that the reason why blocks are not made to ems instead of eighths of inches is lack of knowledge of the point system and block-mounting being relegated to unskilled and semi-skilled labour. How often is the printer annoyed to find the illustration, when placed in a page of type, all "awry," out of perspective, simply because vertical lines in the picture have not been kept parallel with the sides of the block; instead of this, one *edge* of the plate has been kept parallel.

This subject can be crystallised by an argument used by a process engraver, who said, "How can a block-maker make his mounts to picas when one printer's picas are different in size to another printer's picas?" This is equalled by another firm who wanted to know what I meant when I asked that a block should be mounted 18 ems by 12 ems American point body.

All that is requisite to remedy this chaos is for the block-maker to gain an elementary knowledge of the compositor's requirements and a general knowledge of the point system. Also to substitute one of Messrs. Stephenson, Blake and Co.'s type scales (which is a foot rule with inches marked on it and also ems and ens in 6 point, 8 point, 10 point, and 12 point). The block mounter would, of course, only need to use the 12 point em measures. The blocks could be mounted in inches as before, but the fractions would be sixths instead of eighths.

The block-maker who would first install this system would not only confer a boon upon the compositor in the saving of justifying, but also reap more business for himself. Any extra cost entailed would be worth paying by the printer.

Machinery would gradually be introduced to economise the block-mounter's time. The saw bench, or shooting block could be ruled in even ems, as a gauge for outting, or the block could be clamped to the shooting block, which could be made to travel, like a lathe bed, past a revolving plane (vertical for finishing the edges of the block) or a revolving rasp. A Miller saw-trimmer is the nearest approach to this suggestion.

A good designer can fill any given space with appropriate design in

any given period or style of ornament. If this is true, why should not Bristol board, etc., be ruled out in even ems and a design made to fill a given number of them?

Similarly, the ground-glass of the process camera could also be ruled in even ems, just light enough so that they would not interfere with the sharpness of the image. If these suggestions were carried out the point system would work automatically as easily as the present system. Small blocks should be mounted on metal.

When the American point system was first introduced here it met with opposition and ridicule. One ring founder issued a catalogue pointing out the method in general use then as being much superior to the innovation. That particular firm to-day cast their types on American point bodies.

It is time the block-maker got a move on. As your journal is the acknowledged leader in the photographic world, I venture to think you will be interested in these remarks.

Apologising for taking up your valuable space, I remain, yours sincerely,

JOHN HURST,

Bronze Medallist, Photo-Mechanical Photog., Session 1910-11,
School of Technology, Manchester.

171, Lowfield Road, Stockport.

P.S.—We once had occasion to have a correction made in a line zinc block (size of block about 10 ins. x 8 ins.). The correction was set up in type, and an ordinary electro-plate made. The zinc-plate was cut away and the electro inserted and mounted in position with rivets or nails. Messrs. Taylor, Garnett, Evans and Co., Redditch, near Stockport, carried this out, and the electrotypist there (Mr. Evans) routed the block sufficiently low to allow both zinc face and electro face to stand type-high. If this fine cutting of wood can be done with the ordinary router in use, it is not an insuperable problem to improve the present system. The root of the problem is "the block-maker requires to know that six picas make one inch," and work to it.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. B. L.—About 8 ft. high and about 6 ft. from the sitter. Exposures with an *f*/6 lens will be somewhere in the neighbourhood of eight to ten seconds, but, of course, it is not possible to give even an approximate idea of the exposure necessary.

W. P. C.—The only suggestion that we can make is that you use glass plates, which are much less easily damaged, and, when you have got them satisfactorily into use, allow of prints stripping as readily as from ferrotypes. We should say glass is used by 90 per cent. of the firms making glossy prints in quantity.

E. B.—The lenses are no good for regular photography, since they are not corrected achromatically. The eye-piece might be used as a long-focus lens with a small stop. We suggest that you should try mounting each lens separately in a tube made of successive folds of brown paper, and see what kind of image you can get with your camera.

M. T. K.—The office of the Retail Businesses (Licensing) Order for Hampshire is 5a, Union Street, Bristol. You are wrong in supposing that a licence under the order allows you to move about from place to place. It is issued only for a business in a particular place. You would want to apply for a new one every time you move.

M. R.—However much you may wish it, we are afraid you cannot make a distinction of name between men working the photo-copy processes and ordinary photographers. To engineers, for whom

the former chiefly work, they are as valuable, in a different way, as the users of a camera. If we were you we should not worry over what seems to us a very trifling matter.

A. M.—The portrait lens is the worst kind of lens for outdoor work, such as groups, etc., as it has poor covering power, and stopping down does not improve it much in this respect. Your best choice is the Ross or the Busch lens. The latter, though called a portrait aplanat, is not a portrait lens of the ordinary kind. We think the prices are not far from the mark at the present time.

H. J. C.—The Raydex of Raydex, Ltd., 71, Lavender Hill, S.W.11. Their booklet of instructions is quite full, and will give you a good idea of the process. The only other two processes of any kind are the Paget and the Autochrome for the making of colour transparencies. Literature relating to these is obtainable from the Paget Prize Plate Co., Watford, Herts, and from Mr. Thos. K. Grant, 89, Great Russell Street, W.C.1.

G. S.—It seems to us that the real question at issue is what is a satisfactory profit to you on the enlargement. Your customer can naturally see for himself in, for example, Raines's catalogue the price which he would have paid them for admittedly first-class work. If that price is considerably lower than yours, the only point which it raises is the proportion of profit which seems necessary to you. That, obviously, is a question which it is impossible for us to deal with.

S. S.—Nothing that you tell us in your letter indicates that you have done anything to part with your copyright in the photographs, and therefore any sale or distribution by way of sale will be an infringement of your copyright and will be actionable. Any dispute which you may have as to your liability to pay for the cards at an enhanced price is an altogether separate matter; the people cannot legally retaliate by making any use whatever of the cards which have been printed.

T. R. G.—The staining is no doubt due to insufficient fixing. With many papers at the present time it is absolutely necessary to put prints through two fixing baths in succession. Very likely also the defect has been aggravated by low temperature of the fixer. If you make it a rule to use two baths, giving the prints ten minutes in each, and at the same time see that the solutions are not colder than 60° to 65° F., we think you will find that prints will no longer be defective.

C. E. F.—Your whitewash was far too thick, and you laid it on too heavily. The chrome alum has made it waterproof, but you can get it off by soaking with vinegar and rubbing with the distemper brush. The vinegar stains a little, but if you got some commercial acetic acid and diluted it you could probably get off a good deal of the white without staining; you would not have to re-coat then. A little sugar in the distemper would prevent cracking.

G. W. C.—The only half-watt lamps which we have used for photography are the Atmos type, made by the General Electric Company. The company has a special department for photographic lamps, and inquiries should be addressed to it at 67, Queen Victoria Street, London, E.C. Other makes of lamp may be equally good, but we cannot speak of them from experience. We cannot give exact current price for the lamps and fittings, but we hear that they have recently been reduced.

L. J.—If on the previous occasion you simply granted rights of reproduction in a single issue of the paper, then certainly the newspaper is liable to pay you a further fee in reference to the recent publication. This assumes that your invoice on the previous occasion was drawn up strictly, and could not now be interpreted as a general assignment of copyright. This is a matter dealt with at greater length than we can do in a letter in the little manual "Photographic Copyright," issued from this office.

R. L. H.—1. It is only common prudence to employ a lawyer to draw up an agreement of partnership. It is less necessary in the case of the purchase of a business, although in some circumstances legal advice is certainly advisable. 2. The 10-in. Planar was listed to cover a $7\frac{1}{2}$ by 5 at full aperture, not 12 by 10. The lens has never been a popular one, and even now, with the present enhanced prices of second-hand lenses, is not worth more than half its original list price, which was £21 10s.

- A. S.—If the negatives intensified with mercuric iodide are re-developed they are of a high degree of permanence, but if not re-developed are liable to go yellow in the course of months or years, although they remain quite good printers. The iodide formula in the "Almanac" does not give such great intensification as that with mercury ammonia, but there are other mercuric iodide formulae which we have published in the "Journal" and "Almanac" from time to time which give a much greater amount of intensification.
- J. H.—1. Impossible to say without reference to a particular subject. With some colour subjects the panchromatic result might be superior to that with N.F. plates, with others, vice versa. 2. Best after prints have been washed for at least half an hour after fixing. If this cannot be done on account of blistering or frilling, the best plan is to use a hardening-fixing bath. 3. We are sorry we have no data of the factor for the "B.J." pyrosoda developer. 4. No harm results through the broken glass remaining in the bottle.
- E. M.—We think you will be running considerable risk in adopting the name "K Studio." The present proprietor, although he may not trade as the "K Studio," undoubtedly acquired (when he bought the business) any goodwill or connection which accrued to him and still benefits him from the previous use of the words "K Studio." If now you use this title we think he will have good ground for taking action against you. Obviously, it is open to you to do what you can to benefit by your previous connection with the "K Studio" without actually taking the name of the latter.
- A. K.—1. Licences for businesses in Chester are dealt with at New Arts Buildings, Liverpool. 2. It should be simply a matter of form in the case of an ex-service man. The object of the Order is to safeguard such men as yourself from interlopers starting businesses in their absence. Each case is investigated on its merits. The office has not published any conditions of the granting of licences. 3. Allowing 5 ft. for the sitter and for the photographer behind the camera, the minimum studio length for full-length cabinets with an 8½-in. lens is 16 ft. With a 10-in. lens it is 20 ft., and with a 12-in. 24 ft.
- B. E.—The dark marks in the prints are plainly due to local imperfect fixation. You can see that such is the case in one specimen from the fact that the patch has a straight line where one print has lain upon another in the fixing bath. We advise you to use a stronger fixing bath than you are doing, namely, 6 ozs. hypo to 20 ozs. water, and to use two baths of this strength in succession. Bath No. 2 should be fairly fresh. As soon as it has been in use for some time it may replace bath No. 1, and a fresh solution taken for No. 2. We think if you do this you will have no further trouble from this cause.
- C. F.—1. As the studio is rather low, the best installation for your purpose is either one of half-watt lamps or the inverted top-light arc of the Westminster Engineering Company, Victoria Road, Willesden Junction, London, N.W. For full-length cabinets in a studio of only 17 ft. in length, the longest focus of lens which you can use is 3½ inches, that is allowing 5 ft. altogether for space behind the sitter and behind the camera. If you can contrive to dispense with, say, 2 ft. of this space, you could use a 10-in. lens, which would be a good deal better. 2. You require a licence, the office for which is 15, Athol Crescent, Edinburgh.
- K. D.—We think it is very doubtful if the staining effect of the metal coating will disappear by use of the tank. It is impossible to say what will remove the stain, for we imagine that the stain-removers which might serve for stain from developer will be quite useless in this case. Apparently the only remedy for what has been done is to have the trough given a thorough coating of some varnish such as asphalt, which will protect the metal from the fixing bath. Even this is not likely to be thoroughly permanent, particularly if acid fixing baths are used in the trough. It seems to us that it is a case where the repairer should be required to make good the damage he has done.
- F. G. F.—So far as we know there is no exact rule or ratio as regards the relative preservative power of sulphite and metabisulphite. Roughly, metabisulphite used instead of sulphite in a developer will give as good preserving effect if its quantity is one-quarter that of the sulphite—e.g., you can certainly replace 8 ozs. of sulphite by 2 ozs. of metabisulphite, probably by considerably less metabisulphite, though the effect varies, we think, with different developers. But as metabisulphite is very much less soluble than sulphite, it does not help matters much as regards making a more concentrated developer. As a matter of fact M.Q. is not well adapted for preparation in very concentrated solution, and we do not think you will find it practicable to make up stronger solutions than those in, for example, the Imperial M.Q. formula.
- V. A.—Evidently the copyright was created under the old Act according to which copyright lasted for the life of the author (your father) and for seven years after his death. Therefore, if your father died seven years before the present Copyright Act came into force—namely, in June, 1912—copyright in all the works which he made has expired, and there is no means of re-creating it. But if your father died less than seven years before June, 1912, copyright may perhaps be prolonged and still be in existence, for the reason that the term of copyright which existed at the time the present Act came into force is determined (according to the new Act) as though this new Act were in force at the time the photographs were taken. According to the new Act, copyright lasts for the definite period of fifty years. From these particulars you should be able to find out for yourself whether copyright still subsists in the photographs taken by your father. You will find further particulars, as regards transfer of ownership, etc., in the manual "Photographic Copyright," issued by our publishers.
- P. T.—It is not practicable to give a definite formula for the iodine-cyanide reducer owing to the great variation in the commercial strength of cyanide, but we can prescribe a working formula which you can apply to such materials as you can purchase. Make a 10 per cent. solution of potassium cyanide, and buy, if you can, the ordinary tincture of iodine from the druggists. If you cannot buy this, dissolve flake iodine in rectified spirit or methylated spirit to a 5 per cent. solution. To make a working reducer, take now, say, 4 oz. of water, add about ½ drachm of the cyanide solution and then the iodine solution a few drops at a time as long as the iodine is decolourised by the cyanide. As soon as a faint yellowish colour persists add a drop or two more of cyanide to remove it. The mixture will be an iodine-cyanide reducer, which very likely may act somewhat too quickly, in which case add water as required to slow its action. If, on the other hand, the action flags, add more cyanide cautiously, and, if that is not sufficient to energise the reducer, add still a little more iodine.

SUMMARY.

A contribution by Major P. R. Burchell, Squadron Leader, Royal Air Force, provides a useful elementary survey of the technical conditions as regards apparatus, aircraft and optical equipment requiring to be fulfilled in any system of aerial photogrammetry. (P. 695.)

Methods of colour-sensitising gelatine emulsions with auramine alone or in conjunction with an isocyanine are the subjects of two recent patent specifications. (P. 699.)

The chapter in the "Practicus" series this week deals further with the carbon printing process, and consists of a large number of hints representing the experience of a very practised worker of the process. (P. 692.)

In a leading article we refer to the combined use of typewriting and processes of photo-mechanical reproduction now being made by New York publishers in the emergency created by the industrial dispute in the printing trade. (P. 690.)

Mr. Vivian Jobling describes and illustrates a neat fitting for camera or lantern slide boxes in the shape of a flush handle. (P. 697.)

A practical paper on the spotting of prints is quoted from our Boston contemporary "American Photography." (P. 694.)

Hints on the choice of a hand camera for professional use are contributed to "Assistants' Notes." (P. 698.)

Some of the means which should be taken to reduce the quantity of working-up on prints are dealt with in an article on page 691.

The death is announced of Mr. S. D. Chalmers, head of the Department of Technical Optics at the Northampton Polytechnic Institute, Clerkenwell. (P. 702.)

Mr. E. W. Parfitt suggests photographing the sun's disc as an interesting method of measuring the focal lengths of lenses. (P. 702.)

Society secretaries who have not yet sent in particulars of their associations for the directory of societies in the forthcoming "B.J. Almanac" are asked to do so without delay. (P. 689.)

The Photographic Fair organised by Mr. Arthur C. Brookes will be held from April 16 to 24 next. (P. 689.)

Some of the causes of white spots on prints from air-balls are the subject of a paragraph on page 690.

An indispensable instrument in the fixing of prints is a paddle of ebonite or hard wood by which each print can be fully immersed on first being put into the fixing-bath. (P. 690.)

Photographing wall tablets, prints for reproduction, exposures in Press photography, repairs of apparatus, and the provisions of the Retail Business (Licensing) Order are the subjects of brief replies to correspondents. (P. 703.)

EX CATHEDRA.

Fair and Congresses. It is now announced that the Photographic Fair organised by Mr. Arthur C. Brookes, of our contemporary, the "Photographic Dealer," will be held at the Horticultural Hall, Westminster, from April 16 to 24 next. Mr. Brookes states that many applications for space by photographic firms have already been received, and that those wishing to be represented at the Fair should communicate with him at as early a date as possible at Sicilian House, Southampton Row, London, W.C.1. During the period of the Fair two congresses will be held and will have their headquarters at the Horticultural Hall. One is that of the Professional Photographers' Association, suggestions for which are invited from its members by the secretary (Mr. S. H. Fry, Frisian House, 5, Highbury Grove, London, N.). An exhibition of professional photography will also be held in conjunction with the P.P.A. Congress. The other conference is that to be arranged by the Photographic Dealers' Association. Its secretary (Mr. A. Oglesby, 37, Bedford Street, W.C.2) will likewise welcome any suggestions of subjects for discussion or features of the congress of particular interest to those engaged in the sale of photographic requisites. With all these attractions timed to be forthcoming within a single week there should be no uncertainty that the Fair itself and the meetings of professional photographers and photographic dealers will secure a full measure of success. Incidentally it should be mentioned that the Chemists' Exhibition will be open on one of the days during which the Photographic Fair is being held at Westminster.

* * *

Directory of Societies. The directory of photographic societies which we compile each year for the "British Journal Almanac" is now very nearly completed for the 1920 edition. We have, however, still to receive particulars from a few societies. Apparently, in the case of some secretaries it is necessary to make application a second and a third time in order to arouse realisation of the fact that a big book like the "Almanac" must close its pages by a definite date in order to ensure punctual publication. Perhaps unwisely, we give society secretaries a longer period of grace than any other class of persons represented in the "Almanac." When every allowance has been made for the transfers of secretaryships as a consequence of the engagement of men during the war, we cannot but think that there is a certain laxity in supplying particulars the publication of which is bound to be of, at any rate, some advantage to a society. In some cases secretaries are good enough to credit us with powers of divination. They return our form simply with the intimation "Particulars as last year," but omit to

tell us the name of the society to which their message relates. In instances such as this, as well as in those where no answer whatever is forthcoming, we are bound to follow our usual custom and to insert the name of the society, followed by the advice that particulars of its present officers, time and place of meeting, etc., have not been ascertainable.

* * *

Import Legislation. So far as can be gathered from a first reading of its complex text, the Bill now before Parliament which is popularly referred to as the Anti-Dumping Bill proposes to stabilise the emergency regulations as regards the importation of certain foreign goods to which reference was made in this column in our issue of August 29 last. Under the Bill the importation of certain goods may be prohibited. These goods are itemised in a schedule to the Bill, and are seen to include synthetic photographic chemicals (pyrogallie acid is specially mentioned, among other organic chemicals) and optical glass, including lenses, prisms, and like optical devices. While it is out of the province of a technical journal to discuss the political aspect of such measures as these, it may certainly be said that the Bill promises to arouse a great deal of opposition, and already its provisions are being made one of the chief features of a by-election. Many who have been convinced Free Traders have, as a result of the war, brought themselves to favour some policy of exclusion directed against enemy goods, but such, of course, is not the purpose of the Bill, the provisions of which, so far as they concern prohibition of importation, are directed against goods of any alien origin. Further comment than this must be postponed until the provisions of the measure are more adequately explored in the course of debate in the House of Commons.

* * *

Bubbles. Much unnecessary work is caused in the finishing of bromide and gaslight prints by allowing minute air-bells to form upon the surface during development. Very often the cause of the tiny white spots is not recognised, as they are attributed to dust upon the negative or even to imaginary defects in the coating of the paper. The most prolific cause is careless wetting of the paper before development. It is a common practice when developing enlargements to place the exposed paper in a dish, and to turn the tap upon it to make it lie flat and to cause the developer to flow evenly. In these circumstances the water becomes charged with tiny bubbles which adhere to the paper and cause the defect complained of. The remedy is to swab the surface with a pad of cotton-wool either while in the water or immediately after immersion in the developer, when the bubbles will be broken and the solution allowed to act properly. Even if the paper be not wetted before development bubbles may be produced by diluting the developer with water drawn from the tap and not allowing time for the bubbles to rise and break. This may occur when a single solution such as Azol is used, or with concentrated stock solutions of amidol or metol-hydroquinone. It may be well to add that bubbles are less likely to appear when a liberal quantity of developer is used than when there is only just enough to cover the surface.

* * *

Print Paddles. A great help to clean working in bromide print is found in the use of a print paddle. This is a rod with a flattened disc or ring at one end, its use being to push the prints well under the surface of the fixing solution, and to move them slightly, without having to contaminate the fingers with hypo. Such instruments have been made in celluloid, but these were rather light and small for professional use,

and most printers have improvised something on their own account, very often a piece of absorbent wood which has rapidly become saturated with hypo and useless for its purpose. A shade better than this is a large wooden spoon about 18 ins. over all, which has been well baked while new, and then saturated with paraffin wax. This is less absorbent, and the rounded bowl is excellent for dabbing on the prints. Effective paddles have been made by taking a stout brass wire, covering it with a pure rubber tube and bending it into the desired shape, the ends when joined being covered with the rubber tube made hypo-proof with patching rubber and solution. Gutta-percha is rarely met with now, but an ideal paddle could be made of gutta-percha tube, which is stiff enough to need no metal support, and even less acted upon by chemicals than rubber.

CALLITYPE: PHOTO-MECHANICAL REPRODUCTION OF LETTERPRESS.

ONE of the results of the deadlock in the New York printing trade has been the resuscitation of a method of "setting" letterpress according to which use is made of photo-mechanical processes for producing the printing surface. The method has been the subject of articles in some of the New York newspapers, by whom it has been described as a sudden discovery, made for the purpose of providing emergency means for the production of newspapers without the aid of hand or machine type-setting. As a matter of fact, both the idea and the first practical application of it are nearly twenty years old. It was in 1901 that a printer, Jacob Backes, devised the system of "setting" letterpress on a typewriter and of making from the type-written original a printing surface by a photo-mechanical process. Mr. Backes, who is still living, gave to this process the name "Callitype," not a very descriptive title, since it means simply "beautiful type." It is, of course, simply another form of the same name (Kallitype) applied to a process of photographic printing with sensitive iron salts, which is still fairly familiar to photographers. It is difficult now to conceive the motive which could have prompted Mr. Backes to have devised an alternative system to ordinary type-setting. At any rate, he produced a periodical called the "American Callityper," several issues of which made their appearance. Speaking from memory we think it was one of these which formed the subject of an appreciation in the "Photogram," whose editor, the late Snowden Ward, with characteristic optimism and enthusiasm, hailed the new departure as a revolution in the production of letterpress periodicals, and as providing an immense new field for the commercial application of photo-mechanical processes. So far as we know, however, nothing more was heard of Callitype until the recent printing dispute in New York provided the occasion for the employment of a process by which publishers could produce printed matter of a kind in circumstances which deprived them of the use of hand-set or machine-set type.

Apparently very few of the New York publishers affected by the strike have turned to utilise this emergency process. We have received only two periodicals for which it has been used, namely, the "Literary Digest" and the "Scientific American." The former, which was the first to employ the method, has its letterpress "written" on a typewriter and photo-engraved line blocks made from such originals upon a somewhat reduced scale. In the case of the "Scientific American" the type-written letterpress is reproduced, apparently on the same scale as the original, by means of photo-litho transfers on to the lithographic stone, the edition of our contemporary being thus run off

on lithographic presses, whereas, presumably, a typographic press is used for the "Literary Digest."

In view of the fact that these means must have been devised at extremely short notice the printed result may, perhaps, be considered fairly satisfactory. At any rate it is clear and readable, and in the case of the reduced reproductions used by the "Literary Digest" does not impress the reader as something altogether different in kind from ordinary type-setting. But in both cases the matter suffers from a defect which arises from the process, and evidently is one which is inevitable in any system of preparing letter-press in the first instance on a typewriter. However carefully the original manuscript may be copied by the typist, it is impossible that the line should end with the same mathematical alignment that is secured in hand or machine setting. The compositor who sets type by hand obtains this exactly equal width of each line by the insertion of "leads" of suitable width between the various words. In setting matter on the Linotype machine, the same result is secured by an extremely beautiful and automatic mechanical device which can best be described as consist-

ing of a series of tapering pieces which are thrust upwards between the separate words in a line, pushing them out to correspond with the limits of the type-space on each side. The Linotype operator has thus only to judge, slightly in advance, the point at which he shall break his line; the machine then comes into action when the line is completed, giving it the exact width which has been chosen for the setting. It is inconceivable that even a typist possessed of the most exceptional powers of judging how to space and divide each line could ever equal the exactitude of the alignment on the right-hand of a printed column which is obtained without any difficulty whatever by the ordinary methods of type-setting. On this ground alone it may be thought that while Callitype may serve the purposes of an emergency it is never likely to prove a serious competitor of the compositor. Standards of form and precision in printing have become so high that the necessarily ragged right-hand edge of a column of letter-press reproduced from a Callitype original is certainly anathema to the printer, and would surely meet with the disapprobation of a large section of the public.

DODGING THE WORKING-UP.

THE production of a good enlargement usually incurs an amount of hand work, sometimes extensive, on either the negative, the dry enlargement, or on both. The greater part of this work might with advantage be replaced by chemical work and by control of the enlargement during exposure.

In the case of hard or flat negatives it is obviously easier to reduce or intensify than to obtain the necessary softness or contrast by means of brush and pencil. When neither reduction nor intensification fits the case, and yet the negative is wanting, perhaps a new one from a glass positive will prove worth while. It sometimes happens that part of a negative only is at fault, the background of a portrait study is too strong, or certain figures in a group are harsher than others, or more prominent. In such cases, effective results can be obtained by blocking out the good portions (on the glass side) and making a very thin transparency of the negative. When this is dry it is bound in register to the negative (the latter having been cleaned of the blocking-out paint) and an enlargement made of the combination.

Any degree of correction, even to a level grey, can be obtained this way; the depth of the transparency decides the degree.

For mechanical treatment during exposure some pieces of thin art mounting, some transparent white paper—similar to that used for negative bags—a piece of fine black netting, another of white mosquito netting, some fine iron wire, a sheet of plate-glass free from flaws and scratches, and a white glass-headed hat-pin will all be found useful.

A most serviceable aid when "dodging" is a vignette holder in the form of a wooden frame mounted on a stand. Made of 2-in. wood, the frame should be of a diameter equal to the length of the largest size commonly made. The base measurements are such as to allow stability with sufficient height to bring the centre of the frame level with the normal position of the lens when the accessory is standing between the lens and the easel. With such a support, far more can be accomplished in the way of vignetting, combining, shading, diffusing, and dodging than can be done with the hand alone, and the operations can be performed with a precision that is impossible when working without a support. It sometimes happens that part of an enlargement requires dodging throughout the exposure, while another part needs treating for a fraction of the time only. In such cases the frame will take one half the

dodging off one's hands, leaving them free to attend to the more delicate bits.

All this sounds more suitable to trade and commercial work than any other kind, and certainly they offer more scope for "dodgments" than studio portraiture does. With the latter, negatives can be standardised more easily, and the need for correction obviated. As a matter of fact, however, skilful control of enlargements is a valuable work anywhere, and of particular value when dealing with copies.

To return to the stock-in-trade, the art mounting has an advantage over ordinary cardboard, inasmuch as it is easily cut to exact shapes for delicate jobs, and at the same time it can be torn for broad vignettes, the fluffy edge being an advantage.

The transparent paper is useful for eliminating part of a picture with the minimum of trouble. For instance, to remove a figure from a group, instead of knifing away the negative or painting out and subsequently aerographing, a vignette is cut so that when laid on the easel it will closely fit the figure which is to be removed. A piece of the transparent paper is cut to the same size and shape as the vignette and fixed with a small trace of gum to the sheet of glass, which has been previously reared against the wooden frame, midway between lens and easel. The paper is placed so that it just diffuses the image of the unrequired figure. To do this it may be necessary to move the frame and glass close up to the easel, and any stopping down should be done first, as the lens aperture controls the effect to some extent. The vignette is held over the figure while an extra exposure is given. This is necessary to compensate for the opacity of the diffusing paper. The result on developing should be a soft grey patch which the b. and w. artist can easily work into the background (or leave alone altogether). The black netting, stretched on the frame with four push pins and placed half-way between easel and lens, will save half the spotting of a large picture or smoothing of a face. To get the maximum effect without appreciably softening contrasts or focus, the size and kind of mesh illustrated should be used. The white mosquito netting will decidedly soften the picture besides smoothing out spots.

The wire is useful to hold cut pieces of card or paper to shade parts of a picture during exposure. The cards can be hung from the frame with drawing pins, and so easily ad-

justed to a nicety. Similar effects can be obtained by using neutral tint water-colour on the glass sheet.

A glass-headed hat pin occasionally comes in handy to print in a dark spot such as the pupil of an eye, but it must be

Actual size illustration to show suitable mesh of black diffusing material.

used with extreme care, or it will defeat its own object. Invaluable in odd cases, careful tests have to be made before using this dodge on one's last sheet of 30 x 40.

Combination pictures can easily be made by the aid of a piece of art mounting cut in two. Each half should be capable of covering that half (of one of the negatives) that is not required. One cut only must be made; whether straight or otherwise, no trimming is permissible. Having focussed up

the required part of one negative on that part of the easel where the image is desired, the unwanted portion is vignetted off with the cut edge of the correct card, which is securely pinned to the frame. After making the exposure and covering the paper—without disturbing its position on the easel—with a thin sheet of black paper, the negative is removed and the other one put in its place. Then the other half of the out card is pinned on the frame with its cut edge exactly coinciding with that of the other. When the join is made as perfect as possible, the first card is carefully removed. The frame must not be disturbed all this time. The second negative can now be focussed up, using a piece of white paper held against the black to focus on. If these operations are carried out with care and the exposures correctly calculated, there will be no trace of the join in the developed enlargement.

In the same way narrow pictures—particularly if they contain water or grass—can be made square, and *vice versa*. Skies and foregrounds can be extended vertically and mountain ranges horizontally. Of course, this means repeating some part of the picture or bringing in some other negative, but both dodges are useful when it is required to fill a given size without cutting anything off, and the dodges, if carefully engineered, are seldom suspected.

The above-mentioned dodges are mostly applicable, under slightly different conditions, to copying, it being quite as practicable to shade or vignette a negative during exposure as it is to treat an enlargement. In some ways it is easier, as the effect can be fairly well judged on the ground glass; and also, as plates, on account of their greater latitude, seem to lend themselves more to this kind of work than papers do.

THE HERMIT.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).

 Telephoto Lenses for Professional Work (Nov. 7).
 Changing Quarters (Nov. 14).
 Carbon Printing (Nov. 21).

CARBON PRINTING.

II.

To work in comfort, it is very necessary to be provided with an efficient squeegee outfit, consisting of a flat squeegee, a stout glass, or zinc, plate, and a piece of thin rubber sheeting. The squeegee may be from 10 to 15 ins. in length, according to the size of the work, as it is necessary for the squeegee to be at least as wide as the print. The rubber strip should be

soft and velvety so that contact can be secured without undue pressure. Roller squeegees are not suitable for carbon printing. The "mounting board," on which the tissue is attached to the temporary support and the developed print to the transfer paper, may be a slab of plate-glass, marble or slate, or a stout plate of zinc supported upon wood. It should be

absolutely flat and non-absorbent of chemicals. The rubber cloth should be about the size of the glass plate and should be soft and free from creases. Some printers use a piece of stout, single transfer paper instead of a cloth. This answers perfectly, but is wasteful, as one piece does not serve for many prints. Eighteen inches square is a useful size for the mounting board and cloth. The squeegeeing apparatus should all be well rinsed in clean water after use. This avoids crystals forming upon the surfaces, which might cause trouble. The blotting-paper should be thick and tough so that it can be used repeatedly. Ordinary blotting is not sufficiently absorbent, and it is too soft when wet to be pleasant to use.

If possible, a square galvanised tank about 4 ins. deep should be used for development. Failing this, an ordinary oval galvanised bath may be used. Shallow dishes allow the water to cool too quickly. A small gas-ring underneath the tank will keep the water to any desired temperature and save much time, as it is not necessary to renew the water often. Even when quite dark it does not affect the prints, and different colours of tissue may be developed together without altering the tints. If the water froths too much after developing a number of prints a bit of yellow soap moved about in it for a few seconds will clear it. A few small leaden weights are useful to keep the exposed tissue below the surface before stripping, but they may only be placed upon the margins of the support and not upon the tissue.

Besides the flexible support, opal glass or grained zinc plates may be used to develop the tissue upon. These must be waxed in the usual way. With new opal there is a tendency to stick, unless the first waxing is very thorough. It is a good plan to wax them and allow them to stand for a week or so before use, then to re-wax them in the ordinary way. Spoiled prints may be scrubbed off opal with a nailbrush if the surface appears clean; they may be waxed and used without other cleaning, but if there is a persistent tint or trace of the image, they must be well rubbed with Monkey brand soap, Panshine, or similar cleanser, till the surface is quite clean again. Flexible support must not be rubbed. Spoiled prints must be removed by transferring in the usual way. Any creased or damaged transfer paper should be saved for this purpose. On the whole, finely ground opal glass is the best temporary support, as it can be used until it is broken, and it improves with use. The developed prints can be set up in racks to dry, and the prints come off flatter than from the flexible supports.

When the print has to be transferred to a rigid permanent support, such as ivory, wood, porcelain, or glass, flexible support must be used, as it would be obviously impossible to squeegee two rigid surfaces together with any hope of separating them again. With such materials a transferring solution, made as follows, must be used: One ounce of Nelson's No. 1 gelatine is soaked for four hours in a pint of water and then dissolved by standing the jar in hot water. To this is added in small quantities at a time twenty grains of chrome alum dissolved in two ounces of hot water, stirring well the while. The surface of the support is coated with this, and when set, but not dry, the print on its flexible support is squeegeed into contact and allowed to dry. A variation of this is to flood the surface with the gelatine solution and squeegee down at once. Of course, in either case the print must be soaked in tepid water until quite limp. The same solution may be used to coat plain glass upon which transparencies for the lantern or for enlarging are to be developed, but in this case the substratum must be allowed to dry upon the glass before using. The chrome gelatine solution will not keep, as it becomes insoluble on setting, so that no more should be prepared than can be used at once.

Single transfer printing differs only from double, inasmuch as the print is transferred directly to the permanent support,

which is usually paper coated with insoluble gelatine. The manipulation is exactly the same as for flexible support, with the exception that the print is alumed immediately after development. The only drawback to this method is that reversed negatives must be used for all subjects which would betray a lateral inversion of the image. In the case of enlargements and copies of pictures taken with a view to carbon printing, this is easily done. For large work where rough-surfaced papers are required, the single transfer is invariably used, as the original surface texture of the paper is preserved, and not flattened out, by contact with a waxed support. Single transfers are usually employed for opal pictures, and in this case no substratum or preparation of the surface is necessary, the ground surface giving sufficient "tooth."

Daylight is usually employed for the production of carbon prints, and it is generally agreed that the best results are so obtained; the electric arc is sometimes used, but unless the tissue is specially sensitised to obtain the maximum of contrast, the prints are apt to be rather flat. I have found the most satisfactory substitute for daylight in the mercury vapour tube, which gives results indistinguishable from daylight. The uniformity of this light is a great advantage, as prints may be made by timing instead of using an actinometer, very even depth being obtainable throughout an order, provided that the sensitiveness of the tissue does not vary. Of the arc lamps, the Northlight printing lamp is, to my mind, superior to the enclosed arc.

Although I have only described one method of drying tissue after sensitising, there are others which are better suited for working on a larger scale. If a large, well-ventilated dark-room be available, the tissue, after having the surplus bichromate solution lightly squeegeed off, may be hung up in the open and allowed to dry spontaneously. Climatic conditions greatly affect the rate of drying, and, as a rule, if the tissue be not thoroughly dry in eight hours, it will become insoluble and useless. Four hours is a good average time for drying, and the temperature should be regulated so that this time is not greatly exceeded. Gas or coke fumes are also likely to cause a partial insolubility known as "tint." This appears in the form of a general fog all over the exposed tissue, including the "safe-edge." In my opinion, the safest and best way to dry tissue is to use a tightly closed metal-lined box or cupboard fitted with racks to carry a number of laths upon which the wet tissue is pinned; below these are one or more large dishes filled with commercial chloride of calcium, say 7 to 14 lb. in each dish. This absorbs the water rapidly, and the tissue dries quickly and evenly and free from all outside influences. If not required at once, the tissue may be safely left in the chamber. My practice was to take it down off the laths, roll it up, and put it into a large calcium tube similar to those used for strong platinum paper. Before use, the tissue should be exposed to an ordinary atmosphere until limp enough to cut without cracking, as cracked tissue is useless. I prefer to cut all tissue into sizes with a card-cutter, as, if torn, as is commonly the practice, there is great danger of little chips of the pigmented gelatine getting between the tissue and the support when mounting, causing spots which are difficult to remove from the finished print. A very quick and easy way of sensitising tissue is to use a spirit sensitiser. This is brushed on to the insensitive tissue with a flannellette "Blanchard brush." The tissue dries in a few minutes, and may be used at once. The solution, with brush and full instructions, may be obtained from the Auto-type Company. I have not obtained results by this method quite equal to those got by the ordinary way of sensitising, but it is convenient when a small quantity of tissue is wanted in a hurry.

PRACTICUS.

SPOTTING PRINTS.

[Although the spotting out of pinhole markings from prints is perhaps the form of "retouching" which is most commonly needed among both amateur and professional photographers, it is perhaps that which those of both classes find a difficulty in doing, or getting done, satisfactorily. Hence the series of very practical hints contained in the following article from our contemporary "American Photography" will find an interested circle of readers among amateur workers as well as in the ranks of photographic assistants.—Eds., "B.J."]

At my work as a commercial artist I handle many photographs. In a year's time I fix up, paste up, and patch up several hundred, if not several thousand. They come in all sizes and colours, from both professional and amateur photographers; they come from the police department, the farmer, and the business man. Some of them are in one piece and some look like a crazy quilt, while many are excellent prints from a technical standpoint. These prints, or those that need to be, are "doctored" so they are suitable for the half-tone process; they are worked up according to their needs or according to the customer's wishes, all the way from taking out a few spots to covering the whole photograph. Out of all these prints there are very few but need some spotting at least. The reason why there are so few prints that do not need spotting or retouching is hard to figure out. I have come to the conclusion that photographers are either careless or lack the necessary knowledge to do the spotting; therefore this article on such an apparently simple subject.

I am going to give the artist's method of retouching and spotting, which differs somewhat from the photographer's in being a little more elaborate as to colours, but at the same time more practical. I am not going into detail on retouching, using the air brush, masks, etc., but am going to explain the artist's method of everyday spotting, using only the small brush and colours.

Any print may be spotted; the matt-finished paper probably takes the colour a little better than the glossy, but the finish is of no material difference, and one should hardly use a grade of paper simply because it is easy to spot, for in the first place there should be no spots. There is a method, however, of preparing a photograph so it will take the colour better, by rubbing the surface with a suitable solution—ox gall, saliva, and gelatine being some of them. I prefer the gelatine. It is bought in thin sheets and melted in a double boiler with as little water as possible. It is then poured into a mould; the lid of a small box will do; when cold it is removed, and it will dry into a hard square piece. When used, a piece of cotton is moistened with water, rubbed on the surface of the gelatine, and then on the surface of the photograph. It serves the purpose of cleaning the print and at the same time leaves a little gelatine, but not enough to make it sticky. Any photograph can be treated in this way, but if it happens to be a platinum print, too much rubbing will mar it. Ordinary gas-light paper can be rubbed very hard without injury.

The tools used are few in number, being one or two good red sable brushes and the colour. The red sable brush is the only

FIG. 1.—Showing red sable brush. Actual size of point with holder partly cut off.

one suitable for this work; it points up well, and the hair is stiff enough to spring back into shape when released from the pressure on the paper. (See fig. 1.)

The colour plays the most important part in successful spotting. The formula given here is for quite a batch; it can be easily cut down to any desired quantity. These are regular water-colours and can be secured at any art store. They come

in the regular size tubes, and are not what are called "retouch colours," which will be mentioned in a later paragraph.

The following colours are needed to make up the stock colour:—

Sepia	4 tubes.
Vandyke brown	3 tubes.
Sap green	2 tubes.
Lamp-black	2 tubes.

The colours are all squeezed out upon a piece of glass or a mixing slab, then thoroughly ground together with a palette knife; a case-knife will do. After being thoroughly mixed, it may be placed in a jar or other receptacle until we are ready to mix the graduated colours. Before mixing our colours it will be well to consider the two kinds of colours with regard to their covering quality or density. They have been named opaque and transparent colours. While any colour is opaque if put on thick enough, it is not necessarily an opaque colour. With the addition of white to the colour it becomes opaque. The advantage of working with opaque colours is that they can be worked one over the other, the light over the dark colour or the dark over the lighter shades. A white spot on a print can be very easily built up with a transparent colour, but if the spot happens to be black it will need a light opaque colour to cover it. With the transparent colours, the white paper showing through the colour makes the lighter shades in proportion to the thickness of the colour on the paper. With opaque colours the shade depends on the proportion of white mixed with the colour.

The method of mixing colours is as follows:—Fig. 2 represents the colour slab that is used most; although it is not absolutely necessary to have one, they are much handier than

FIG. 2.—Showing the five-section slab in which the various tints needed for spotting are mixed.

sauces or a sheet of glass. The graduated colours range from the stock colour No. 1 to the lightest colour No. 5, which is nearly white. The white is obtained in tubes or small jars. There will be more white used than any other colour, so it is best to buy it in small jars. Any good grade water-colour white will do. A jar of the white is put on the mixing slab and just a touch of stock colour is mixed in with it, which will give a very light grey. About one-fifth of this is put on the slab for the No. 5 colour. You are now ready to mix the No. 4 colour. A little more of the stock colour is mixed with the remaining colour on the slab and we have colour No. 4, and so on, each time adding a little stock colour, until we get to colour No. 1, which is nearly all stock colour. The idea is to get the colours evenly graduated from the lightest down to the darkest.

Another way which might be easier to graduate them evenly: Mix No. 1 and No. 5 first, then No. 3 half-way between these two, and then the two remaining colours. Besides the five graduated colours on the slab, we sometimes need pure black and pure white, which are generally kept separate in small jars. The best pure black is what is known as "retouch brown." It is brown only when thinned out with water, and it will cover the blackest kind of glossy print. It is used only to touch out white spots on the darkest shadows on glossy prints; on any other prints the darkest colour on the slab will be dark enough. Retouch brown dries with a gloss; the other colours dry with a dead finish.

The manner of applying the colour to the print is something that comes through practice, and is rather hard to explain. The brush is dipped in the colour the full length of the hair and then wiped partly dry and rubbed on the colour. The whole brush should be thoroughly moist with colour or it will not point up properly. A blotter or rag should be handy to wipe off part of the colour if the brush will not come to a fine point. After a little practice it is easy to judge how much colour and how much water to combine to get the proper point.

Probably the part that requires the most skill is matching the different tones on the photograph with the retouch colour. Here is where the graduated colours are a great help. With white and black and the five colours on the slab, it will be much easier to find the right shade than when using only one or two colours. These colours are mixed for the average warm black-and-white gaslight print. If the print is of sepia tone a little more Vandyke brown added to the colour while mixing with the brush will help to get the proper shade. The way to apply the colour to the spots without its being noticeable depends on the size of the spot. A small spot will need only one touch of the brush to eliminate it, but the larger ones are not quite so easy to get rid of. To cover the larger ones and place the colour smoothly is best accomplished by stippling. This

simply means to fill in the space by the use of small dots until it is a solid mass to the naked eye, but if put under a magnifying glass it would appear something as shown in fig. 3. This represents the filling in of a light spot with a darker colour. Fig. 4 represents the filling in of a dark spot with a lighter colour. If the colour does not match on the

FIG. 3.—Magnified image of light spot filled with dark colour.

FIG. 4.—Magnified image of dark spot filled with light colour.

first application, it can be removed with a little moist cotton on the end of a brush handle. If only a small part of the colour is off, it is not necessary to remove the whole of it, but it may be touched up with a lighter or darker colour, whichever it needs. This is another advantage of working with opaque colours; the dark colour can always be covered with the light, or vice versa. Too much colour should not be applied; the thinner the coat the smoother the surface. If it cannot be matched with one or two applications it is best to clean it off and go over it again. A spot much larger than one-sixteenth of an inch can hardly be handled successfully with a hand brush; an air brush is needed.

After all is written about spots and spotting, it is much easier and simpler to say: to avoid spots, clean the negative thoroughly and keep it free from dust and lint, and you have the best preventive for spots, one which is better and quicker than all the water-colour remedies ever patented.

S. H. AVERY.

AN ELEMENTARY SURVEY OF THE PRESENT POSITION OF AERIAL PHOTOGRAMMETRY.

1. Definition.

Aerial photogrammetry may be defined as the science of applying aerial photography to the making of maps.

2. Employment of Photogrammetry Outside Aviation.

Typical examples of the employment of photogrammetry outside aviation are:—

- (a) Photographic survey largely used in Canada and elsewhere.
- (b) The Bertillon method of photographically recording scenes of crime.

3. Employment of Photogrammetry in Conjunction with Aviation.

There is little doubt that ultimately photogrammetry will be largely used as a cheap, rapid and accurate instrument for making maps, showing distances, contours, and minute topographical detail.

Aerial photogrammetry has grown up almost entirely during the war and its problems have been partially solved as they arose. Like every method of survey it has its limitations, and although it would be absurd to imagine it entirely supplanting more usual methods, there is no doubt that it can almost always be of tremendous assistance.

For every individual tract of country to be surveyed, before deciding to use aerial photogrammetry, it will be necessary to determine among other things:—

- (a) How much of the work is already done, and whether the data is sufficient for the aerial photogrammetrist to complete the work.
- (b) Whether the country is better suited physically to ground survey than to aerial survey.
- (c) The relative cost of the two methods.

4. Some Features of the Ideal Camera for Aerial Photogrammetry.

In the ideal apparatus provision should be made for recording accurately and automatically upon every photograph—

- (a) The compass bearing.
- (b) The altitude of the instrument above a known datum plane.
- (c) The hour.
- (d) The direction and degree of tilt of the optical axis as regards the vertical.
- (e) The optical centre of the photograph (i.e., the intersection of the principal optical axis and the sensitive surface).

It is essential that the principal focal length be accurately known, and that the sensitive surface be strictly flat and perpendicular to the principal optical axis.

It is further very desirable that some simple stabilising device (gyroscopic perhaps) be incorporated, so that, with a view to minimising correctional work, the optical axis will remain as far as possible in the direction desired.

The lens should preferably be a highly corrected type of wide aperture. The selection of its focal length will depend upon the particular type of work in hand.

The sensitive surface should preferably be panchromatic and of high speed, coupled with very fine grain. The base of the sensitive surface may be either rigid or flexible. The relative advantages and disadvantages of celluloid film are summarised below.

ADVANTAGES.

Adaptability to automatic drive.
Lightness.
Small bulk.

DISADVANTAGES.

Difficulty of securing flatness.
Awkwardness in subsequent handling.
Difficulty in keeping good panchromatism and high speed.

It is very desirable that the changing of plates or films should alter the position of the centre of gravity of the camera as little as possible. Many semi-automatic plate-changing cameras do not possess this feature.

The focal-plane shutter is usually regarded as superior to other types for aerial work. Among its many advantages may be mentioned the fact that a "kick" of quick period vibration occurring during exposure will result only in a band of "movement" appearing on the photograph, whereas other types would show movement all over the photograph.

The changing of the sensitive material should preferably be automatic, either wind-driven or motor-driven.

The exposure is perhaps preferably made by the operator, but the automatic succession of exposures is often advocated.

The moving parts and plates should be so housed that swing and tilt of the camera will not cause displacement. Gravity-fed cameras almost invariably suffer occasional jams through violent turning movements of the aircraft.

The selection of size and shape of the plate or film employed will depend upon the type of work in hand, the focal length used, and the altitude from which it is proposed to work. Weight and bulk also will, of course, need consideration.

5. *Photographic Technique.*

Commercial lenses, plates, paper and chemicals, and light filters offer so wide a range of usefulness that in aerial photography no very marked departure from everyday practice is necessary.

6. *Compass, Altimeter, and Clock.*

Any forms of these instruments that are compact and accurate are suitable, and they should preferably be mounted in an accessible position so that they can readily be adjusted. There is no great difficulty in mounting them so that their readings are automatically recorded upon the photograph.

The compass and altimeter should not possess any undue lag in recording changes.

7. *Inclinometers.*

In the absence of proved apparatus for maintaining the principal optical axis truly vertical some form of inclinometer is desirable. Centrifugal force may at any time cause this instrument's readings to be inaccurate, but its errors will not necessarily be persistent. While aircraft is actually engaged upon photography flying must be as straight and free from "stunts" as possible, and in such circumstances inclinometer readings may probably be very nearly accurate. There exist many neat types of instruments (gravity worked) which can be mounted inside the camera, and which will give readings of the degree and direction of inclination.

8. *The Carrying Aircraft.*

- (a) High-powered small aeroplanes present great handicaps by reason of vibration and necessary limiting of weight, dimensions and working space of the apparatus. Further, their rapid turns, climb and descent are liable to cause displacement of the photographic apparatus.
- (b) Medium and large size aeroplanes remove the handicaps of weight and space limitation, and in them a bay largely free from engine vibration is usually available for the apparatus. In flying they are steady and probably are the best type for war-time photogrammetry.
- (c) Absence of vibration and small centrifugal stresses from pitch, roll and yaw are qualities which might render the small *lighter-than-air* craft suitable for peace-time, and particularly oblique, work

9. *The Camera Mounting.*

Attention must be paid to:—

- (a) Security.
- (b) Absence of vibration and wind pressure
- (c) Cleanliness.
- (d) Accessibility.

Until the difficulties besetting gyroscopic and other stabilisers are completely overcome it is probably good policy to mount the camera so that it is either rigid with the aircraft or limited to a small range of movement in relation to the aircraft. For the cure of vibration troubles both methods have their advocates, and both have been

successfully employed. Mountings on some form of cushion principle (either spring, rubber or pneumatic) are probably the most generally satisfactory.

10. *Stabilisers.*

In warfare the loop, vertical bank, vertical dive, spin, roll, etc., are common evolutions. Any stabilising device designed to maintain the optical axis vertical during such evolutions must necessarily be on the "gimbal" or some similar principle (it is obvious, for example, that a ball and socket support or suspension will not suffice), and the gimbal would need to be of such a size that the camera had space for a complete "somersault" in every direction. It would be necessary also that the camera controls (drive, release, etc.) had provision for complete revolution in every direction.

Even with a gimbal fitting possessing these features it is very certain that gravity alone would not exert sufficient force to overcome the centrifugal force of, say, a loop. In addition to the centrifugal stresses set up in aeroplanes by pitch, roll or yaw (which stresses are, of course, much more violent in aircraft than in watercraft) it is necessary to overcome a swinging pendulum motion that may be at times set up by variable pull or thrust of the air screw, and it is probable that "bumps" also would exert some peculiar stress. The solution that immediately suggests itself is the gyroscope. But it is very doubtful whether any gyroscopic device yet designed would overcome all the complicated stresses that may be involved. And it should be remembered that a shock of stress to a gyroscopic stabiliser will under certain conditions result in a persistent alteration of the datum plane in which it is desired to maintain the optical axis.

Any stabiliser that does not completely overcome any and all of the stresses to which the camera *may* in practice be subject would be a source of danger if relied upon in photogrammetric work. Even in peace flying some incident in taking off or climbing might upset the datum plane of the instrument, and out of a false sense of security large errors in mapping might ensue.

The best working method at present is one in which the camera's optical axis is normally perpendicular to the flying-level line of the aeroplane, and in which provision is made for the damping of vibration and for the free swinging of the camera through about 10 deg. in every direction from the vertical. Under such a system of mounting the careful co-operation of the pilot in keeping the aeroplane on a level keel will usually limit the unwanted angle of tilt to, say, 4 deg. from the truly vertical. The use of *mean* photogrammetrically determined positions for terrestrial points will prevent the occurrence of any undue cumulative errors.

11. *The Position of the Principal Optical Axis.*

The principal optical axis in the ground photo. survey in Canada, and in the Bertillon method mentioned above, is maintained in a horizontal or nearly horizontal plane. In aerial photogrammetry such a position is unsuitable because of the necessity for using an extremely wide-angle lens, and because even the foreground of the photograph would be very distant. In aerial photogrammetry, however, when the axis is truly vertical, map-making is extremely simple so long as the photographed territory contains two known points and a sufficient number of other points suitable for addition to the map. Difficulty is experienced under this last head in desert regions. Where the optical axis is not vertical there is, of course, no reason why any side of the rectangular plate should be parallel with the ground; but where the amount and direction of tilt of the optical axis is known the correction of the photograph for mapping presents no great difficulty, and several workers have evolved systems and apparatus for the purpose. Where the amount and direction of tilt of the optical axis is not accurately known, so long as the photograph contains a sufficient number, say four, of known points, the amount and direction of tilt can be determined, and the distortion can be corrected.

In order to save a large amount of work, however, it is highly important that the following factors should be known with the greatest possible accuracy:—

- (a) Altitude of the camera above some known point included in the photograph (*i.e.*, above some known datum plane).
- (b) The focal length of the lens.
- (c) The direction and amount of tilt of the optical axis.

12. Multiple Lenses.

Various forms of aircraft camera have been designed carrying more than one objective. The object in some has been to include in photographs taken simultaneously the horizon in two different compass directions (opposed at, say, 90 deg.), so that from the position of the horizon upon the photographs the tilt of the optical axis would be immediately determined. The difficulty here is that when working from any great height, and on days at all misty, the horizon line cannot be fixed upon aerial photographs with any approach to accuracy. The object in other cases was to photograph as much territory as possible simultaneously (partly obliquely and partly vertically), so that from the position of the images of many known points could be deduced the position of the other points. One such camera is the Panorama-Apparat of Scheimpflug, which, however, is cumbersome, and its utility has not been fully established.

As an alternative it has been suggested that a ground camera and an aerial camera should photograph each other's positions simultaneously, so that from the position of the image of the aircraft upon a vertical plate exposed on the ground, and the position of the image of the ground camera upon the oblique plate exposed in the air, triangles would be available from which all the data as regards tilt, etc., could be deduced. There are many objections to this scheme, the chief of which is perhaps that the ground camera would need to be so far forward, and would need to make so many changes of station, that in place of the aircraft a ground photo-theodolite or the plane-table might be used with more ease and almost equal effect.

13. Ground Contour.

Oblique aerial photographs studied comparatively yield useful data as to contour. Assume that two photographs are taken obliquely from different view-points, but each including common territory. When a sufficient number of image-points from each have been made to coincide when plotted upon the map, assume that there is some point included in each photograph the images of which will not coincide when plotted upon the map. It is obvious that the altitude of that point is different from the altitude of the other points, and it is clear that if we plot both images upon the map and join each position to the point immediately beneath the camera at the moment of exposure, the intersection of the two lines will be the true position of the point upon the map. It is also clear that the altitude of the point can be calculated from the amount of displacement that occurred.

Some years ago the Zeiss Stereo-Micrometer and the Zeiss-Pulfrich Stereo-Komparator were introduced for the study of contour. These instruments can be used for the measurement of differences in level made visible when paired aerial photographs are viewed in the stereoscope. After sufficient tests, much is hoped from the practical employment in aerial photogrammetric work of a simplified form of the latter instrument.

14. Conclusion.

Many thoughtless people have the impression that for map-making a few hundred aerial photographs are all that is required.

Many surveyors, on the other hand, with well-proved faith in their excellent instruments, rather disdain the aerial photograph.

Meanwhile inventors are busy improving aircraft and photogrammetric apparatus, and mathematicians are busy working out and simplifying systems of correction.

The whole subject contains a fascination, and as soon as the cheapness and accuracy of its employment have been demonstrated it is safe to prophesy a speedy recognition and appreciation of its value.

THE ZEISS FIRM, OF JENA, according to a newspaper report, has been forced to close down its works temporarily through lack of coal.

A FLUSH HANDLE FOR CAMERAS, INSTRUMENT CASES AND LANTERN SLIDE BOXES.

MANY are the instances in which the projection of handle or handle-fittings proves an inconvenience on a camera, and a distinct disadvantage on an instrument case or lantern slide box, when it may be desired to store one on top of another. The handle shown in the sketches entirely overcomes such difficulties, and, being of simple form, can be fitted by anyone of comparatively small mechanical skill. The only operation requiring such skill is the making of the

recess to receive the handle; this, however, can be readily done by the aid of a small chisel, if the outline is first cut to the required depth with a sharp-pointed knife. The actual handle can be cut from a scrap of saddlers' leather or a portion of an old strap, a leather punch or small cork borer being useful, but not essential, for making the hole and the ends of the slots. The bridges are made from strip brass 3/8 in. by 1-16 in., being secured by No. 6 wood thread screws of about 1/2 in. length if the thickness of wood will allow. If, however, the wood is thin, it is better to secure

Cross section showing recess in wood.

the bridges by metal thread screws and nuts, as shown in the alternative sketch. Suitable 1/4 in. screws 1/2 in. long, with square nuts, known as pressed nuts, cost only a few pence per dozen, and are useful in many other ways for repairing apparatus, etc.

If the camera, case, or box is thin (say, not exceeding 3-16 in. thick), the recess can be cut through and backed up inside by a piece of thin wood, sheet metal, or even cardboard, the backing being held in position by the screws and nuts which secure the bridges.

The dimensions given in the sketch are those which will be found suitable for a small and compact handle, yet large enough to take the hand of an average man (say, the wearer of a size eight glove). Should a larger handle be required, it is only necessary to increase the distance between the bridges by 1/2 in. to 1 in. without altering the sliding movement. The handle shown in the sketch is as

Alternative section for thin cases.

arranged for fitting lengthwise to a box-form camera. If, however, it is required for use on a symmetrical case, the sliding movement may be arranged half at each end without altering the proportions.

Where symmetry is not required for the sake of appearances it is well worth the slight additional trouble to fit a handle so that an

equal balance is obtained, as the added comfort in carrying a magazine hand-camera so arranged is quite appreciable. It is only necessary to suspend the camera or case horizontally in a string sling and then mark the point of suspension as the centre of the handle.

VIVIAN JOBLING.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Hand-Cameras for the Professional.

A VARIED experience in professional photography has led me to the conclusion that the hand-camera is a much under-valued and under-used instrument, and it is the purpose of this article to point out a few of the many ways in which it may be useful, to give some hints as to the selection of an outfit, and, lastly, to give a few practical tips as to its use. I know it is the habit of many "pros," especially middle and upper class men, to look down on the hand-camera as something below their notice. This is a pity, because there are many cases in which it is the best possible instrument, and some cases when results can only be got by its use.

The ways in which a hand-camera may be useful to the average "pro." may be classed under three main heads:—(1) The taking of topical events; (2) photographing from positions in which a stand camera is impossible; and (3) in the photographing of restless children and animals.

Many studios look with small favour on topical events—processions, opening ceremonies, football matches, etc.—and yet they are great business-makers. They are really a wonderful chance of an advertisement which will not only not cost you anything, but will bring you a handsome profit if worked on the right lines. Every studio needs this, something to remind the public of their business. Get a good negative, print it well, and do not forget to put your name plainly upon it. Let people see where it comes from, and then if they like the print they will want to know more about you.

To take our second point. In the course of a photographic lifetime one comes across quite a number of jobs which one would like to refuse, and often enough the trouble is to get the camera where it is wanted. Let us suppose that a photograph is wanted of a house from a river. The opposite bank is impossible, and it is essential to get the near bank in. What is to be done? If you get a Dreadnought moored in the river for you, you might get a decent stand-camera negative, or if you don't mind standing in four feet of water you might do it; but if you want the best result with the least trouble you get a hand-camera and use it from a punt or other small boat.

Now, to refuse such a job as this is confession of incompetence. "Why," your customer will most likely tell you, "I've taken it myself with a Brownie, only I want a big one now." No, it won't do to refuse the job; but to try it with a stand outfit will be worse still, because a bad result is worse advertisement than no result at all.

Now for our last class—or, rather, two classes—children and animals. Never try to take a restless child in the studio if an outdoor appointment can be made. The strangeness of the studio and the restraint of having to sit still destroy all chance of a natural result, unless one can spend hours over the job. By making use of a hand-camera out of doors perfectly natural studies can be obtained. The background may be blocked out on the negative or a well-chosen natural background may be left—it is quite as satisfactory as many studio productions. The lighting may be controlled to a great extent by taking advantage of building, trees, etc., and the occasional use of temporary screens and reflectors.

The use of a hand-camera in the taking of dogs, horses, cattle, etc., outdoors saves much time. Trying to photograph a restless horse with a stand outfit is one of the most trying jobs you can get; but use a hand-camera and it is easy, and again the results gain much in "naturalness."

There are three types of camera suitable for a professional—reflex, collapsible focal-plane, and hand-stand. The one to get depends on the class of work it will be chiefly used for. The reflex is by far the best for taking children and animals where close-up studies are needed. The ease with which the normal lens is changed

for one of longer focus is an advantage not to be overlooked. The disadvantages of a reflex are three: bulk, the fact that it has to be used at waist level, and that, except in the finest instruments, the jar of the mirror going up prevents very slow speeds being used without camera shake being obvious on the negatives.

The collapsible focal-plane is a most useful camera for street work and for any objects at a moderate distance. It has the advantages of being light and easily got ready for work. Its disadvantages are two: it usually has very limited extension, and it is not easy to substitute a lens of different focal length. When one lens only is needed, and that for fairly distant objects, this type will be found perfectly satisfactory. The hand-stand type of camera is useful chiefly when it is desired to take only one camera, and yet be prepared for ordinary stand work and "snapshots." It is a remarkably efficient instrument, and when fitted with a focal-plane shutter is really ideal for most work. The only point against it is the fact that the use of more than one lens means the use of more than one focussing scale, a state of things which often leads to mistakes.

A question that is sure to arise at this point is, "What size?" Half-plate is generally the smallest size plate used by professionals, so that many will choose this. That has the additional advantage of making your new lens an addition of some value to your stand camera set, or it may mean you do not have to purchase a new lens at all. In spite of this, I think half-plate rather too big. Not only is the camera itself bulky to hold, but the plates are expensive, and there is bound to be a larger proportion of "wasters" with a hand outfit than with a stand one. I think 5 x 4, or even quarter-plate, will be found quite big enough for the average job, the results being enlarged whenever it is thought necessary.

Now as to hints on working. To begin with, get rid of any idea you may have about hand-camera negatives being inferior to stand ones. They can be first-class if only you take the same trouble over them as you do over your ordinary work. Your negatives *must* be sharp, because in most cases they will have to stand enlargement. This means a good lens, accurate focussing, and, above all, a steady camera. Find out what is the largest exposure you can give without shake, and stick to that, except when movement of your subject necessitates speeding up. You are not likely to over-expose "snaps," but you *will* under-expose unless you are careful.

You can, of course, use your ordinary developer, or you can make up a special one. I have found nothing better for under-exposed negatives than the pyro-metol formula given in the "British Journal Almanac." This certainly brings more detail out in a negative than the average pyro-soda.

When you have got your negatives, don't say, "Anything will do for those snapshots." Take the same care over the retouching, printing, and enlarging as you do in the case of studio negatives, and you will shortly find that hand-camera negatives may not only be as good, but also as profitable, as any others.—ARTHUR G. WILLIS.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR-SENSITIVE EMULSIONS.—No. 133,769 (October 15, 1918).—

According to the invention the colour-sensitised material comprises a light-sensitive emulsion containing a dye of the auramine or iminodiphenyl methane class (i.e., substitution derivatives of benzophenoneimide).

The chemical formula for the principal member of the class is $(N(CH_3)_2C_6H_4)_2C=NH$, and it is to be understood that one or both of the two dimethylamido groups may be replaced by hydrogen or organic radicals, and that any one or more of the remaining nine hydrogen atoms in this typical compound may be replaced by another atom or group such as chlorine, the amido group, the ethyl group, and others, to form other dyes of this class.

It has before been proposed to use auramine in the emulsion of an orthochromatic plate in sufficient quantity solely for the purpose of reducing the action of blue light on the plate in the same way as tartrazine and other yellow dyes are used in making self-screened or non-filter orthochromatic plates, but auramine has no apparent colour sensitising effect when used with dyes of the eosine group, or with any other colour-sensitising dye known at the time when it was thus proposed to employ auramine.

Heretofore it has not been known that dyes of this class, of which auramine is the chief representative, had any colour-sensitising effect. This is perhaps due to the sensitising action of this dye (auramine) occurring in the blue region of the spectrum.

The inventors have found that if auramine is applied to a chloride emulsion it makes it strongly sensitive to the blue region of the spectrum, and that it also has a just perceptible sensitising effect on the ordinary fast bromide emulsions.

The dye may be used in about the ordinary proportions for colour-sensitising, which is only from one-tenth to one-fortieth of the quantities used for screening purposes. For example, if a plate is to be treated by the bathing process, it is immersed for three or four minutes in a solution of 1 gm. of auramine, or another dye of the same class, to 50,000 c.c.s. of water.

If desired, part of the water may be replaced by alcohol and a few drops of ammonia may be added per 1,000 c.c.s. of the bath, these variations being already known in connection with the immersion of photographic materials for colour-sensitising.

If the dye is added to the melted emulsion, it may be added in the proportion of .005—.025 gms. per litre of emulsion.—Frank Forster Renwick, Sunnyside, Weald Road, Brentwood, Essex, and Olaf Bloch, 44, Finsbury Square, London, E.C.2.

COLOUR-SENSITIVE EMULSIONS.—No. 133,770 (October 15, 1918).—

This invention has for its object to provide material which shall have either a different or greater colour-sensitiveness than has heretofore been obtainable.

In patent No. 133,769 means are described for obtaining a plate having either a different or a greater colour-sensitiveness than those at present existing by means of using a dye of the auramine class, which is defined as the auramine of iminodiphenyl methane class, i.e., substitution derivatives of benzophenoneimide.

According to the present invention, the colour-sensitised material comprises a light-sensitive emulsion containing a dye of the auramine class, together with one or more dyes of the isocyanine class, such for example as pinacyanol, now known as "sensitol red."

The choice of the isocyanine dye or dyes added to that of the auramine class depends upon the effect required. For example, with pinacyanol, improved red and green sensitiveness is obtained

and also new sensitiveness to deep red is produced which is not found with pinacyanol alone.

The proportion of the dyes used are similar to those already employed for colour-sensitising materials. For example, if a dry plate is to be sensitised by the bathing process, it may be immersed for three or four minutes in a bath composed of 100,000 c.c.s. of water, 2 gms. of the dye of the auramine class, and 2 gms. of the isocyanine dye.

If the dyes are to be mixed with the melted emulsion, then from .005 to .025 gms. of each dye is used per litre of emulsion.

In some cases it may be desired to use the dye of the auramine or iminodiphenyl methane class in sufficiently large proportions, for example, 20 gms. to the 100,000 c.c.s. bath instead of 2 gms., or .25 gms. per litre of emulsion instead of .005 to .025 gms. to operate as a screen as well as a sensitiser.

It will be understood that in the bathing process the usual variations consist in the substitution of some alcohol for some of the water, and the addition of some ammonia may be made.

According to the invention, with combinations of auramine and pinacyanol and other combinations of the same two classes, the character of the sensitiveness is changed and improved, and is not such as would be expected, but usually different from and much greater than the sum of the effects of the separate dyes. Moreover, other valuable photographic qualities are introduced or improved, for example, good-keeping properties and cleanliness. Further, it is found that when the dye of the auramine class is employed in conjunction with the isocyanine dyes and in sufficient quantity to act as a screen as well as a sensitiser, it still markedly improves the colour-sensitiveness conferred as well as exerting its screening effect.—Frank Forster Renwick, Sunnyside, Weald Road, Brentwood, Essex, and Olaf Bloch, 44, Finsbury Square, London E.C.2.

AUTOMATIC SHUTTER RELEASES.—No. 133,015 (September 21,

1908). The shutter release comprises a casing 1 adapted to be attached directly to the shutter-casing, and containing driving mechanism, the driving mechanism being connected to a member 8 passing through the aperture by which the casing 1 is secured to the shutter-casing, and directly operating the shutter mechanism. As shown, the casing 1 is connected to the shutter-casing by a tube 9 rotatably mounted in a socket on the casing 1, and the member 8 consists of a wire. The tube 9 may be rigid or flexible,

Fig. 1.

Fig. 2.

and may be immovably attached to the casing 1. The driving mechanism, after being wound up, may rotate a pinion 3 to actuate a rack bar 4 bearing a single disc 7, as shown in Fig. 1, or may rotate a disc 12, to which is pivoted at x a holder 13 secured to the wire 8, as shown in Fig. 2. If the tube 9 is flexible, a support, comprising a bar having clips at each end, or compris-

ing two relatively adjustable members 16, 17, Fig. 5, having clips 15, may be provided to hold it in position.—David Friedmann, 16, St. Annagasse, Zurich, Switzerland.

SUB-MARINE PHOTOGRAPHIC EFFECTS.—No. 134,046 (October 29, 1918). The invention consists in providing a tank for the production of photographic under-sea effects, the tank having a solid back wall, side walls provided with windows, and a front wall provided with a single window disposed between the top, bottom, and side edges thereof.—Frank Douglas Williams, 715, West 169th Street, New York.

ROLL-FILM.—No. 134,013 (October 21, 1918). The sensitive film is transversely cemented to the band at intervals, the film having at each side of and close to the line of cement an indication of where the film may be cut, as with scissors. The indications may consist of lines lightly printed upon the film. The length of each portion of band from one cemented point to the next exceeds the length of film between the same two points, so that when any section of the film is in position for exposure the portion of band that is behind the section will be slack, the pull of the band being transmitted to the film through the cemented points, so as to hold the section taut and flat.

The film and its opaque carrying-band are wound as usual on the carrying roll for marketing, and the end of the band has a terminal for connection with the usual winding-up roll of the camera. The end of the film nearest the terminal of the band may be secured to the band in the usual manner, as by a cemented transverse strip.

All of the sections can be successively exposed and then developed in the customary manner without separation of any sections, as the film is continuous. If, however, it is desired to develop the first one or more of the sections without waiting until all sections have been exposed, the user can, in the dark-room, detach the one or more sections that have been exposed by cutting on the lines. As the carrying band remains intact, and as the unexposed sections are attached thereto, the whole can be returned to the camera with the band terminal re-connected to the winding-up roll.—Irvin Maurice Kelley, 48, Baldwin Street, Laconia, New Hampshire, United States.

Trade Names and Marks.

REGISTRATIONS RENEWED.

EAGLE (DESIGN).—No. 278,595. By C. Zimmermann, trading as Charles Zimmermann and Co., in 1906. (Class 1.)

AUTOKON.—No. 278,102. By John J. Griffin and Sons, Ltd., in 1905. (Class 8.)

GOLDONA.—No. 278,134. By John J. Griffin and Sons, Ltd., in 1905. (Class 39.)

SCIPLETTE.—No. 276,116. By T. S. Bruce in 1905. (Class 39.)

IMPERIAL (LION LABEL DEVICE).—No. 158,934. By the Imperial Dry Plate Co. in 1891. (Class 1.)

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is of course the method adopted by a firm having no further occasion for the use of a mark.

CELVEREX.—No. 275,854. Registered by R. and J. Beck, Ltd., in 1905. (Class 8.)

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—Members of the P.P.A. may be reminded that between now and the second Friday in January next, namely, January 9, they may exercise their rights in the way of nominating members for the position of President and members of Council. A member may nominate one person as President and not more than twenty-four persons as members of Council. Under the rules of the Professional Photographers' Association any member nominated to an office is notified of the fact by the secretary, and if no reply is received within four days the member is assumed to have signified his consent. Election is by ballot, the ballot papers being collected at the annual general meeting. Nominations should be sent to the honorary secretary, **Mr. S. H. Fry**, 5, Highbury Grove, London, N.5.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, DECEMBER 1.

South London Photographic Society. "Photography and the Pantry; or, How a Photographer Got Even with His Wife." H. Creighton Beckett.
Dewsbury Photographic Society. "Self-Toning Papers." N. Ruddlesden.
Willenden Photographic Society. "Table-Top Photography." E. W. Brookes.
Bradford Photographic Society. Members' Lantern Slide Night.
Kidderminster and District Photographic Society. "Trimming." H. W. West.

TUESDAY, DECEMBER 2.

Royal Photographic Society. "Demonstration of Lantern Slide-making." A. H. Lisett.
Haekney Photographic Society. "Work on Negatives and Prints." W. Selfe.
Doncaster Camera Club. Lantern Lecture: "In Cromwell's Land—Huntingdonshire." F. Thorne.
Chelsea Photographic Society. "Foothills of the Eastern Alps." D. Johnson.
Dennistonn Amateur Photographic Association. Whist Drive.
Sheffield Photographic Society. "An Evening Walk." A. Keighley.
Manchester Amateur Photographic Society. "Demonstration on Gaslight Papers." J. E. Hadfield.
South Glasgow Camera Club. Lantern Lecture.

WEDNESDAY, DECEMBER 3.

Croydon Camera Club. "Camera Records from the Zoological Gardens." D. Seth-Smith, F.Z.S.
North Middlesex Photographic Society. "Enlarging." H. Stanton, Night Outing Print Competition.
Edinburgh Photographic Society. "Some Autochrome Pictures." W. E. Redding.
Dennistonn Amateur Photographic Association. "Pleasant Hours with a V.P.K." G. Clare, Print Criticism.
Partick Camera Club. "Camping and Tramping in the Highlands." T. Lochhead, G. and D.P.U. Visit.
South Sutherland Photographic Society. "Make Your Own Printing Paper." I. Nixon.
Halifax Scientific Society. "The Amateur Photographer" and "Photography" Prize Slides.

THURSDAY, DECEMBER 4.

Hammersmith (Hampshire House) Photographic Society. "Experiences of a War Photographer." H. C. Beckett.
The Camera Club. "1,500 Miles through Great Russia, Little Russia, and the Caucasus." W. Barnes Stevan, M.J.I.
Richmond Camera Club. "A Demonstration of the Ozobrome Process." T. Manly.
Brighouse Photographic and Naturalist Society. "The Yorkshire Coast from Flamborough to Runswick Bay." H. P. Kendall.
Aston Photographic Society. "Pictorial Composition." F. W. Pidditch.
Wimbledon Camera Club. Lecture with slides: Ilford Panchromatic Plates.
Hull Photographic Society. "Lantern Slide Making." J. W. Atkinson.
Dundee and East of Scotland Photographic Association. "The Fascination of Florence." Rev. J. R. Forgan.
Rodley and District Photographic Society. "Bromide Enlarging." Messrs. E. and J. G. Farrar.

FRIDAY, DECEMBER 5.

Dennistonn Amateur Photographic Association. "Intensification and Reduction." A. Robertson.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held at 35, Russell Square, on Friday, November 14, 1919. Present: A. Basil, Gordon Chase, A. Corbett, C. F. Dickinson, Alfred Ellis, S. H. Fry, W. E. Gray, Reginald Haines, R. N. Speaight, Lang Sums, F. G. Wakefield (London members), Marcus Adams (Reading), Frank Brown (Leicester), W. B. Chaplin (Windsor), T. Chidley (Chester), W. Illingworth (Northampton), F. Read (Southport). Letters of regret for non-attendance were read from Montague Cooper (Taunton) and H. C. Spink (Brighton).

The minutes of the meetings held on October 10 and 23 were read and confirmed.

The Finance Committee recommended the payment of accounts amounting to £16 odd, and these payments were authorised by the Council.

At the instance of Mr. Illingworth the advantages of incorporation were again discussed. Mr. Illingworth read and complained of a paragraph in the circular (page 300) on the subject; he suggested that the paragraph had been written by some of the members of the Council in collusion to oppose his action. Mr. Fry stated that he had written the paragraph without assistance, and that read in the ordinary and natural meaning of the words it represented the present position of the matter, and was favourable to Mr. Illingworth's suggestion of incorporation at some future time. He himself was in favour of some form of incorporation, but thought the time not quite ripe for action.

Mr. Illingworth pressed for a decision in the matter. Mr. Frank Brown discussed the matter, and quoted a legal opinion he had

obtained. After referring to associations of some important professional bodies, which were acting under Parliamentary powers or Royal Charters, he said that the Professional Photographers' Association existed for the benefit of master photographers, and one could hardly make comparisons between it and the associations to which he had referred. The great point was to maintain the usefulness of the Association for the benefit of men who were making their livings at the business.

Mr. St. George doubted if the matter of incorporation were really urgent, but Mr. Illingworth was sure it was urgent.

Mr. Haines believed that most of the members of the Council were in favour of incorporation, and stated that he was pretty sure they should find that they would have to incorporate, but stated that he was dead against incorporation at the moment. In this remark he was supported by Mr. Rawd.

Thereupon Mr. Illingworth accepted the suggestion that the matter be deferred, but not dropped.

The proof copies of the new edition of the handbook, with additional matter—the whole written and revised by Mr. Mackie—were then discussed in detail, and subsequently passed for printing. A letter of appreciation to Mr. Mackie for his work was ordered to be sent to him by the Hon. Secretary.

Mr. Illingworth moved, and Mr. Chaplin seconded, a motion that a special general meeting of the Association be held on December 12 at 6 p.m., at 35, Russell Square, for the purpose of so altering the rules as to empower the Council to engage a paid secretary; and the Hon. Secretary was instructed to send out the proper formal notices to the members.

Congress.—A Committee, consisting of Messrs. Speaight, Basil, Marcus Adams, Lang Sims, and the officers of the Association, was appointed to make the necessary arrangements.

Objectionable photographs.—The Council had before them a letter from a member thanking a member of the Council for drawing his attention to photographs of bathers at a South Coast watering place, and stating that the local municipal authorities were dealing with the matter to prevent a repetition of the vulgarity.

The next meeting of the Council will be held on Friday, December 12, immediately after the conclusion of the special general meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 25, Mr. C. H. Oakden in the chair.

In the course of a lecture on "No" and other things Japanese, Mr. C. P. Crowther gave a most interesting description of the character and origin of the performances known as "No," and consisting partly of a play and partly of a highly perfected form of very slow dancing, which are attended with the very greatest interest by the more cultured of Japanese. As a performance the "No" dates from some hundreds of years back, and its traditions have been preserved with very great accuracy through the art of its acting and dancing having been handed down from father to son in many families of professional performers. The original costumes and masks used by their ancestors as remote as twenty generations were employed on the "No" stage at the present time. From what Mr. Crowther said "No" is evidently the choice of the elect. Its performance, beginning at nine o'clock in the morning and lasting throughout the day, will be watched with the same degree of interest as that with which a highly musical audience will follow grand opera. Yet some idea of the deliberation of the dancing is conveyed by the fact that in a dance lasting forty minutes a "No" performer may not make more than sixty steps. Mr. Crowther illustrated the costumes of the "No" performers by photographs of his own and by Japanese drawings.

Passing to other things Japanese, he gave a short account of other folk plays less solemn in character than the "No," and frequently acted at intervals during a "No" performance to lighten the proceedings; also of the marionette plays which were very ancient performances in Japan, and were shown without any concealment of the figure and hands of the men controlling the movements of the puppets. Mr. Crowther came in the end to a brief but very interesting talk on a few of the manners and customs of Japan and on past and present conditions of living, taken from his experience of twenty-five years in the country.

A most cordial vote of thanks was accorded to him.

CROYDON CAMERA CLUB.

DR. C. ATKIN SWAN re-entered a congenial, albeit not an ecclesiastical, atmosphere last week with a repetition of a lantern-lecture, embracing sunny and smelly scenes in Algeria. Mrs. Atkin Swan having expressed a strong wish to visit Croydon and inspect the "weird collection of oddities" (*vide* the "Walrus"), the rules and regulations relating to the maintenance of peace and harmony by the exclusion of the feminine sex were relaxed, and she and another fair visitor were cordially welcomed by a crowded audience. It cannot be said the doctor appeared cowed, but he certainly was on best behaviour, and despite this handicap scored heavily as usual.

He began in customary fashion by going for the "office boy," with a suggestion that this inoffensive personage should hazard a guess on every slide shown as to its panchromatic origin, or the opposite, and pay a dollar forfeit to the club funds with every "bloomer" made. The making of bloomers at a minus rate of pay was promptly declined, though on "Heads I win, tails you lose" principles the club would have stood nicely.

The only real clash of arms arose on the question of mirages, the doctor mentioning he had attempted to photograph them and failed. "The sort of mirages you observed possibly never could be photographed," enigmatically observed a member; but it transpired that many have attempted to record these curious optical phenomena without success. One operator in Turkey, it was stated, time after time had vainly endeavoured to photograph them. To add to the puzzle, in some cases at least, the mirage can be seen on the focusing screen.

The doctor's theory on the subject could only be grasped by specialists in his own line of thinking, but it was dimly gathered that mirages were possibly composed of chunks out of the ultra-violet and yellow of the spectrum reacting on each other. Its basis on an analogy of fluorescence, due to impact of X-rays on certain substances, led Mr. Jobling to endorse this view. The optical Mr. Reynolds was then asked to speak. He rose, feebly murmured something about the highly original nature of the opinions expressed, and succumbed. Mr. Ackroyd thought that the failure of the plate to record a mirage arose from the fact that the strong white light shining through it obliterated the aerial mirage, and this commonplace explanation was considered to be probably correct. If there are any readers abroad who have specialised in the mirage business it would be interesting to have their experiences. Even as a side-line, it does not appear to be a paying proposition. A most hearty vote of thanks was accorded the lecturer with much acclamation.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice of intended dividend is given in the estate of John Page Croft, photographic paper and apparatus maker, etc., Packwood, Grove Avenue, Moseley, Worcester, and carrying on business at Cooksey Road, Small Heath, Birmingham, also at 24, Quadrant Chambers, New Street, Birmingham, and Alfred Roffey, photographic paper and apparatus maker, etc., residing and carrying on business at 586, Coventry Road, Small Heath, Birmingham, also carrying on business at 394, Cooksey Road, Small Heath, Birmingham. Proofs must be lodged on or before November 29 with A. S. Cully, Official Receiver, Ruskin Chambers, 191, Corporation Street, Birmingham.

A first and final dividend of 1s. 2½d. in the £ has been declared in the estate of the Louvre Studios, Limited, 127, Earl's Court Road, Earl's Court, London. The dividend is payable at the office of the Official Receiver and Liquidator, 33, Carey Street, Lincoln's Inn, W.C.2.

NEW COMPANIES.

KOROH CO., LIMITED.—This private company was registered on November 17, with a capital of £2,000 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in photographic materials and optical goods, etc. The first directors are D. Norman, 269, Crosby Road, Seaforth; G. W. Black, 38,

Moss Grove, Liverpool; J. Oates, 269, Crosby Road, Seaforth. Solicitors: McAusland and Airey, 8, Victoria Street, Liverpool.

DYE IMPRESSION PHOTOS, LIMITED.—This private company was registered on November 12, with a capital of £5,000 in £1 shares (2,500 pref.). Objects: To acquire letters patent and provisional protection patent rights and inventions relating to dye impression photography, cinematography, or photography of any kind, etc. The subscribers (each with one share) are F. W. Donisthorpe, 87, Lauderdale Mansions, Maida Vale, W., photographic expert; W. H. Edridge, 24, St. Mary Abbott's Terrace, Kensington, W., consulting engineer. The first directors are F. W. Donisthorpe and W. H. Edridge. Registered office: 24, St. Mary Abbott's Terrace, Kensington, W.

News and Notes.

MAIDSTONE PHOTOGRAPHIC SOCIETY.—A new photographic association, affiliated to the Maidstone Church Institute, has been established under this name. The President is Mr. H. W. Witcombe and the secretary, Mr. H. E. Lilby, The Gables, Loose, near Maidstone. Meetings are held every Tuesday at the Church Institute, Maidstone.

PHOTOGRAPHS OF SPITZBERGEN.—Messrs. Speaight, Ltd., have informed us that an exhibition of photographs of Spitzbergen, taken by Mr. Richard N. Speaight, was to be opened at Messrs. Speaight's premises, 157, New Bond Street, London, W.1., by Sir Martin Conway, M.P., on Wednesday, November 26. The photographs are shown by permission of the Northern Exploration Company, Ltd., the undertaking interested in the winning of coal and other minerals from the deposits in Spitzbergen.

EASTMAN KODAK WAR MEMORIALS.—On November 12 and 13 last, so we read in the "Rochester Democrat," memorials were unveiled in the works of the Eastman Kodak Company to those employees who had undertaken military service, and more particularly to those who had fallen. The memorials took the form of nickel silver tablets engraved with the names of the employees in silver against a black background. Mr. George Eastman presided over the ceremonies, which took place in various sections of the works. Altogether, from the different branches of the factory and in the executive offices, there were 980 employees engaged on military service, of whom twenty-two were killed.

DEATH OF MR. S. D. CHALMERS.—We regret to see the announcement of the death, on November 7 last, of Mr. S. D. Chalmers, head of the Department of Technical Optics at the Northampton Polytechnic Institute, Clerkenwell, and a past President of the Optical Society. An Australian by birth, Mr. Chalmers graduated at the University of Sydney, and subsequently at Cambridge, where he was thirteenth Wrangler. During the war he had been very actively engaged, not only in important scientific work for the Ministry of Munitions, but also in the organisation of workshops for the training of girls as grinders and polishers of lenses. The strain of this work, in addition to his regular duties, was no doubt a chief cause of his death at the early age of forty-two.

THE 1920 ABDULLA ALMANAC.—For the wall almanac issued by them for the forthcoming year, Messrs. Abdulla and Co., the well-known firm of cigarette-makers, have enlisted the help of a number of artists of distinction, whose work, reproduced in colour, forms a very attractive series of sheets. Among these artists are Reginald E. Higgins, R.B.A., Noel Pocock, Imis Meo (Italy), K. Miyake (Japan), and F. Sancha (Spain). It deserves to be prominently mentioned that 20,000 copies of this almanac are offered for sale for the benefit of the British Red Cross Society, which, it is hoped, will benefit to the amount of £1,000. The almanac may be obtained through any tobacconist or post free from Messrs. Abdulla, 173, New Bond Street, London, W.1, price 1s. 4d.

X-RAY WORK.—An exhibition of prints illustrative of the employment of the X-ray is being organised by the Röntgen Society, who have accepted an invitation of the Royal Photographic Society to provide a collection of such prints to form an exhibition at the Royal Photographic Society's House, 35, Russell Square, W.C., from January 6 to February 7, 1920.

The exhibition will be open daily (admission free) from 11 a.m. to 5 p.m., and on the evenings of January 6 and January 13 till 9 p.m. On the former date an elementary lecture on "The X-Rays Approached from the Popular Standpoint" will be given by Dr. George H. Rodman, and on January 13 a discussion will be opened by Major G. W. C. Kaye, O.B.E., M.A., D.Sc., on "Some Aspects of Radiology."

ARTIFICIAL DAYLIGHT.—At a meeting of the Illuminating Engineering Society held on Tuesday evening last a demonstration was given by Mr. L. C. Martin, lecturer in the Technical Optics Department of the Imperial College of Science, of an invention for providing illumination identical with that of normal daylight. The correction of the illumination from an artificial light-source for this purpose is carried out by reflection of the rays of light from a screen consisting of small patches of various colours. Such an invention has many useful applications in the visual matching of colours. It is doubtful whether a similar source of light of power sufficient for studio portraiture would really be very greatly to the photographer's advantage. At present equally good portraiture is done by lights of such different spectral composition as open and enclosed arcs and mercury vapour, but there are no doubt aesthetic reasons for the adoption of a light identical with daylight in its visual effects.

QUANTITY ONE-MAN TANK DEVELOPERS.

To the Editors.

Gentlemen.—I do not often take exception to anything in the "B.J.," but, having a one-man business myself, I think there must be something wrong in "Assistants' Notes," page 679, of November 2. There Mr. A. G. Willis says:—"The owner of a one-man business is busy operating all day; at perhaps about 9 p.m. he finds himself faced with the task of developing, let us say, 160 half-plates."

First, supposing he works ten hours in the studio; 160 half-plates means sixteen plates an hour, and, supposing he takes two of each sitter, means about 7½ sitters, taking eight minutes for each sitter (in the hour). To fill up the slides and do this in eight minutes for each person wants some doing. It must be cheap work, or clients would not put up with it. I have seen some of the quick-taking places, and they take about five minutes average for each. Then, if he is a one-man business, when is he going to do his printing or anything else, unless he puts it out?

Second, there is a little misunderstanding about the time developing. If he has two tanks, twenty-five plates each, he could not do them in half an hour with ordinary tank development, as they should stop in there for that time at the least, and longer (weaker development) is better—at least, I have always understood so.

My opinion about it is this: If the man has that amount of plates to take every day he could, and should, do with at least three or four assistants, and he could well afford them, unless he was taking them at cost price.—Yours truly,

Barnet, Herts.

A. ENGLAND.

MEASURING FOCAL LENGTH.

To the Editors.

Gentlemen,—As the various methods of obtaining the focal lengths of objectives seem to be of general interest and value, may I be allowed to state one system that I do not remember to have seen mentioned hitherto? It is this:—Take a negative of the sun, and, when developed, measure as accurately as possible the diameter of the solar image (preferably by means of the microscope). Now this quantity, whatever it may be, divided by .0093 will give the equivalent focal length of the lens employed. The system depends on the

fact that the angular measure of the sun's diameter at mean distance is 32 minutes of arc, and the constant .0093 is the sine of this angle. April and October are the best times for making the tests, as the sun is then at about its mean distance, but if made at other times of the year the error is practically so small as to be negligible. A slow "process" or lantern plate, backed, should be used and a quick shutter exposure given, and it is best to focus the camera on a distant terrestrial object, as it is somewhat difficult to focus on the sun itself on account of the glare. For every inch of focus the diameter of the sun's image = .0093 in.

An example will show the method. Supposing the image produced measures $\frac{1}{10}$ in. = 1/10 in. diameter, then $\frac{1}{10} = 10 \cdot 752 \text{ in.} = \text{focal length} \cdot 0093$

Of course, one can equally well use the metric measures. For instance, supposing the equivalent focal length of a telephoto lens is required, and, after proceeding as above, the image measures 18 mm.,

$$\text{Then } \frac{18}{0093} = 1935 \text{ m.m.}$$

The first example shows that a very useful rule to remember is that 10 $\frac{1}{2}$ in. of focus is required for every 1-10 in. of image of the sun's disc.

Don't use a focal-plane shutter in the summer for this, as a hole may be burnt in the material.

Trusting that this method will be of interest and somewhat novel.
—Yours sincerely,
EDWARD W. PARFITT.
Tufnell Park, London, N.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—With reference to the assistant question, I should like to offer the following suggestions as a practical attempt to get something done instead, as seems to be the general attitude, of waiting for someone else to do it. If someone in London will take the matter up there, there is no reason why we should not succeed, and, once started, it should not be difficult to develop. I suggest that an organisation on the following lines would probably best meet our special conditions:—

(1) Every town where the number of assistants warrants it, such as Liverpool, Manchester, Leeds, etc., forms a local branch, which would deal with minor local affairs direct, and in other matters act in an advisory capacity and as local intelligence department of a county committee.

(2) Every county forms an association, composed of representatives elected by the whole of the members in the county, with an executive committee which could deal with matters affecting the county generally. In towns where there is no local branch the members would deal direct with the county committee.

(3) A national executive, with headquarters in London, which would deal with questions affecting assistants as a whole, and give its support, where necessary, to the county organisation in purely county affairs.

By an organisation on these lines (3) would give us a national standing, enabling us to deal directly with Government Departments, etc.; (2) would give us a strong body on the spot able to deal with authority and promptitude on county affairs, and supplied with up-to-date and reliable information by (1), which would ensure local conditions being fully understood and presented in the proper quarters.

So far as Liverpool is concerned, there is no need to go to any expense in hiring a meeting-room for a preliminary discussion. Any assistant sufficiently interested in his own welfare need only attend at the premises of the Everton Camera Club, 3, Village Street, at 3 o'clock on Thursday next, where he will find others eagerly awaiting his support.

But, for goodness' sake, do something yourself, and do not expect God to provide. He provides for the rich and powerful, no doubt, but the poor must provide for themselves.

Apologising for the length of this letter,

"ANOTHER HOPEFUL."

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

M. M.—It is rather a doubtful point if you require a licence, but if you do the office to which you should apply is 99, Queen's Gate, South Kensington, S.W.7. They will advise you if it is required.

C. A.—We think the Retail Businesses (Licensing) Office for your district (Essex) is 80, Westbourne Terrace, Paddington. If this is not correct the Paddington office will forward it to the proper quarters.

R. S. R.—With artificial light the exposure varies in direct proportion to the power of the light, so that 3,000 c.p. would require double the exposure of 6,000 c.p., the same lens and plate being used. We should advise the diffusing arrangement to be about 4 ft. long, 2 $\frac{1}{2}$ ft. deep, and 2 ft. front to back.

R. E. G.—So far as we understand the Trade Marks Act, you cannot register a word in reference to a business, but only in reference to some product which you make or sell. If you write to the Controller of Patents, 25, Southampton Buildings, Chancery Lane, W.C., you can get a circular of instructions for applying for a trade mark to be placed upon the register.

T. and Co.—Photographs are most usually printed on watch dials by the carbon process. If you write to the Autotype Co., 74, New Oxford Street, London, W.C.1, they will give you any information on specific points. The book on making ceramic miniatures is "Photographic Enamels," by R. D'Hellecourt, published by Messrs. Hiffe and Sons, Ltd., 20, Tudor Street, London, E.C., price 2s. 6d.

S. B.—If you want fairly stiff celluloid, and wish to buy in fairly large quantities, the best firms are Messrs. Guiterman and Co., 35-36, Aldermanbury, London, E.C.2, and the Centuple Manufacturing Co., 55, Wilson Street, London, E.C. Celluloid of very much thinner substance is sold by Messrs. Rheinlander and Son, New Malden, Surrey, who perhaps could also supply the stiff in small quantities.

J. G.—The plan you suggest would not mend matters. What you want to do is to fix up some kind of open-ended muslin tent or tunnel against the tablet, pointing the camera into the tunnel, so to speak, in making the photograph. If you can rig up this arrangement, then you can use flashlight with advantage on one or both sides of the tunnel as necessary to reduce the length of exposure or give relief to the lettering.

W. H.—In order to make photographs, either by artificial light or daylight, with the effect of fireside lighting, you want an artificial fireplace through which the day or artificial light can be admitted, and which is used in conjunction with general illumination in the room. The best advice we can give you is to write to the Vanguard Co., Maidenhead, for reprint of an article from the "B.J." on this very subject. It is obtainable free.

F. O'B.—With so small a working space as 15 ft. you must not have a longer focus lens than 8 ins. This is allowing 5 ft. for the sitter and for space behind the camera. If you can make do with a foot or two less for these purposes you could have a 9-in. lens, which would be better. As 8 ins. is a short focus for covering a half-plate, the lens would have to be of the anastigmat type, e.g., one of the f/4.5 anastigmats.

W. M. M.—The best answer we can make to your question is to refer you to the Secretary of the Edinburgh Professional Photographers' Association, Mr. Felham Moffatt, 125, Princes Street, Edinburgh. This association has recently been taking up the

question of apprenticeship and of instruction to photographic assistants, and from among its members, or from among other photographers, could perhaps give you the help you want.

D. and H.—1. We think you can get the kind of half-watt lamps you require from the Thornton-Pickard Manufacturing Co., who supply one for moderate degrees of enlargement. 2. We have sent you the table you refer to, taken from an old "Almanac," but we have discontinued inserting it for the reason that the indications are absolutely without any value owing to the different ways in which H. and D. numbers are supplied by different plate-makers.

J. E. L.—For the highest class of half-tone blocks most photo-engravers prefer a toned P.O.P. print of glossy surface, although glossy untinted bromide prints are very largely used chiefly for blocks of somewhat coarser ruling used for newspaper illustration. In the case of reproduction in collotype and photogravure, it is usual for the negatives to be placed with the reproduction firm for them to make prints or transparencies for their purpose.

R. L.—You can probably get a new spindle from either Mr. R. E. Feeling, 4-5, Holborn Circus, London, E.C., or from Mr. H. T. Ball, 54, Berwick Street, Oxford Street, London, W.1. There are scores of patents for focal-plane shutters. Your only course would be to search through the specifications at the Stirling Library in Glasgow with the help of the sectional classified indexes, which are issued by the Patent Office to institutions where the specifications are on view.

F. J.—We are afraid there is no ready means of treating prints so that they will curl in the opposite direction. Usually prints are put to dry on a net, stretched on a frame, with the film surface in contact with the net, and when fairly dry, but still limp, are put under pressure between glass plates for a few hours. If treated in this way they will remain fairly flat. Mr. Stokes, in the article which we printed in our issue of October 17, described a press for applying the pressure.

A. D.—1. We are not sure, but we think the paper is made by Cassio, Ltd., Watford, Herts. The firm previously had the name of Baryta, Ltd. 2. About the best plan, although it is tedious, is to squeegee gelatine prints over the whole surface of the glasses, and then get them off again either by stripping (if they will strip) or by soaking in hot water, if they won't. This seems to get glasses into proper condition better than any other method, but it might be worth while first to try scrubbing the glasses with a little strong nitric acid, which you can best apply with some glass wool, purchasable from a chemist's.

A. H. S.—1. You will find ordinary glazier's putty the easiest to use for repairing the balustrade; after you have mended all the holes, give the whole thing a coat of lead colour paint, well thinned with turpentine; this will prevent gloss. If you buy the paint in a tin, do not shake it, but pour off the oil and thin the thick paint with turpentine only. 2. The false lights in the eyes show that you are not careful in placing your reflector. You can see the lights on the ground glass before you expose, so that you must move the reflector or the sitter until they disappear. If the reflector is not at fault, it may be some other white object in the studio.

W. S.—1. Few quarter-plate reflex cameras have a big enough front to take an 8-in. $f/4.5$ lens. Our experience is that there is not a very great practical advantage in having an 8-in. lens of such large aperture. For the sake of depth, it so often happens that you have to stop down, so that you might just as well content yourself with, say, an $f/6$ lens, at which aperture you could get the focal length that you are seeking. 2. We do not think very much of either of your pyro-soda formulæ, as we do not agree with the practice of mixing the sulphite and carbonate together in the B solution. If this is done, the sulphite deteriorates very much more rapidly, and does not then preserve the mixed or working developer so well.

R. R.—We do not know of any single lamp which will give a properly diffused light for portraits which will permit of $\frac{1}{4}$ th second with a lens working at $f/7.7$. As some indication of the power of the half-watt lamps we would say that with six 1,000 c.p. lamps and a lens working at $f/3.5$ we have obtained good negatives in

$\frac{1}{4}$ second. The enclosed arc gives a more actinic light than the half-watt, and a single large Westminster lamp would come nearest to your requirements. If this is placed in the position shown in your sketch it should give fairly good light. Have the lamps to raise and lower, as by lowering you will be able to give shorter exposures for sitting figures and children than if at full height, which should be about 7 ft. 6 ins. to the arc. Our advice is to get a quicker lens if you must give such brief exposures. The decoration of the studio will tend to make the most of the light.

W. G. A.—1. Without knowing anything of the situation and surroundings of the studio, we advise you to use plain glass with casement curtains over it. The alternative is to have ground-glass or ribbed glass, but both of these obstruct light and may cut down your light at times of the year when it will be a great disadvantage. It is impossible to say more without knowing the compass bearings of the studio, and whether it is shut in from any quarter by other buildings. 2. A panchromatic plate and screen is of no advantage. The best plate for the purpose is one of the slow landscape variety of about 50 to 100 H. and D. A process plate is rather too slow. 3. Theoretically the back should be swung so that the plate is vertical, but very often it is an advantage for the sake of depth of focus at a large aperture to disregard this and to do so usually has no ill effect upon the "drawing" of the portrait.

G. S. L.—So far as we know, the pressmen have no secret methods. Probably in circumstances such as you mention a lens-aperture of $f/4.5$ would be used, and for the sake of depth a much smaller camera than half-plate, say 5 by 4, $\frac{1}{4}$ -plate, or even one of the Verascope cameras such as are commonly used for portraiture in the bad light of the Law Courts, in each case resort being had to enlargement up to half-plate or whole-plate size. We doubt if it is customary to use a much more rapid plate than yours, although for exceptionally bad conditions a very fast plate is undoubtedly of value. Nevertheless the value of ultra speed can be over-rated, since you cannot do so much in the way of "forcing" the exposure in development. Probably the pressmen use most of their skill in developing, pyro-metol used about half-strength and distinctly warm, about 70 degs. F., being employed, together with some patience, in getting the utmost out of the exposure. So far as we know, there is nothing for it but combining methods on these lines.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed adv'ts should reach the Publishers on Monday morning.
The insertion of an advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In some notes on the chromium intensifier Mr. Raymond E. Crowther discusses the recent paper by MM. Lumière and Seyewetz, and points out that a solution made up with potassium bichromate and hydrobromic acid is an effective bleacher in the process. (P. 709.)

Many inquiries continue to reach us in regard to the licence which is necessary for the starting of a new retail business such as a photographic studio. In a leading article we endeavour to make clear what is the present position under the Retail Businesses (Licensing) Order, and offer our opinion on one or two of the debatable cases which have arisen. (P. 706.)

The article this week by "Practicus" deals with some of the less appreciated points in connection with bromide printing. Our contributor lays stress on freedom of the developer from hypo, and has some hints to give on the improvement of defective bromides by toning and other means. (P. 707.)

Some of the expedients of American photographers in interesting children in the productions of their studios are the subject of an article by Mr. Ernest A. Dench. (P. 710.)

Some of the thin glass which is now being used for plates of fair size may easily be broken in use. One or two precautionary measures are the subject of a paragraph on page 705.

Low temperature in developing during the present cold weather may easily be confused with under-exposure as regards its effects. (P. 706.)

At the Royal College of Science Chemical Society last week a bath which fixes plates in thirty seconds was demonstrated. A brief report of the meeting appears on page 711. A result of this kind is probably obtained by addition of accelerators of fixing to the hypo. (P. 705.)

At the next annual meeting of the Royal Photographic Society the question of raising the subscription to members who join after December 31 next, and who reside within thirty miles of London, will come up for discussion. (P. 708.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article Mr. R. M. Fanstone has some practical hints to give on the making of lantern-slides by the Autochrome and, particularly the Paget, screen-plate processes. (P. 45.)

Particulars have now been filed at the Patent Office, where they are available for inspection, of the colour process associated with the name of the Russian inventor Prokudin-Gorsky. (P. 48.)

Detailed particulars have been given in a recent specification of Mr. J. T. Smith of a method of making two-colour screen-plate filter films of a degree of fineness which, it is claimed, is sufficient for cinematograph projection. (P. 46.)

EX CATHEDRA.

Rapid Fixing. On another page will be found a short report of a meeting of the Royal College of Science Chemical Society, at which Mr. K. Hickman demonstrated the use of a fixing bath of his invention which was shown to fix effectively in 30 seconds. Without knowing more than is contained in the report, it may be surmised that this result is obtained not by the discovery of a more energetic fixing agent than hyposulphite of soda, but by addition of other substances to a hypo fixing bath of maximum fixing power. The late Mr. Welborne Piper carried out and published in these pages a large number of experiments on this question. Having found that the strength of hypo solution which fixes most quickly is one of 40 per cent., he proceeded to test the effect, as regards speed of fixing, of various additions, and found that ammonium chloride and ammonium sulphocyanide are two salts which increase the speed of fixing to a substantial degree. Of the two, ammonium chloride is the most satisfactory; the softening action of ammonium sulphocyanide on gelatine is a serious objection to its use, although, apart from this, it permits of very rapid fixation. With ammonium chloride, on the other hand, a hypo bath of 20 per cent. strength containing from 2½ to 5 per cent. ammonium chloride was found to fix in two minutes, which is getting fairly close to the result obtained by Mr. Hickman.

* * *

Thin Glass

We do not yet appear to be receiving anything like pre-war supplies of glass, judging from the thickness, or rather thinness, of some of the larger sizes of plates. We recently opened a box of 10 x 8 plates which were about the thickness which would formerly have been classed as "extra thin for use in sheaths" for hand-camera work. Considerable care is necessary to carry through the ordinary operations of development, fixing and washing, but it is only in the printing-room that actual danger appears. The slightest inequality in the printing frame or a very slight jar is often sufficient to cause a fracture, with all the attendant trouble of binding up, dodging in printing, and spotting the copies. It is a wise precaution to have all frames fitted with a piece of patent plate or at all events a good stout cleaned-off negative glass. This is a great protection and will often save the negative in the event of the frame being dropped. In order that the glasses may be always kept in position it is a good plan to wedge them in with strips of wood dipped in seccotine or other glue. Such glass also serves to keep the pads and backs of the frames clean and flat, while they are also useful for supporting small negatives which are to be vignettted upon large paper. For this purpose a thin card frame to keep the negative from slipping about will be found very convenient.

Cold Solutions and Shadow Detail.

It is not fully realised by many photographers that with the approach of the colder weather they should give special attention to the temperature of their solutions. In the case of plates, not only does development with a cold solution take a very long time, but when this condition exists certain ingredients of the developer such as hydroquinone almost cease action altogether. If the solutions are kept in an unheated dark-room care should be taken to see that they are not used at a temperature lower than 50°. We have seen negatives developed with a cold solution which though possessing full density, were lacking in the shadow details and gave the impression that they were considerably under-exposed when the reverse was actually the case. It is a good plan to add a very small quantity of hot water to each lot of developer and fixing solution or to stand the bottles in a warm room for some time before use. Of course, if the dark-room is properly heated the solutions will never fall below an effective working temperature, and this latter is the proper course to be followed for the sake of the plates, no less than for the mere comfort of those who handle them.

LICENCES FOR NEW RETAIL BUSINESSES.

THE ministerial order which goes by the name of the Retail Businesses (Licensing) Order is one of those pieces of emergency war legislation which has not been repealed, and appears now, if our correspondence is any evidence, to give rise to more inquiries and doubts than in the early stage of its existence. Although it was recently mentioned by the Minister of Labour in the House of Commons that the question of dispensing with the necessity of obtaining licences before retail businesses could be opened was "under consideration," that explanation, like many other official replies in the same form of words, may be taken for what it is worth. We were informed not very long ago by an officer employed in the administration of the Order that it would certainly remain in operation until March next. Inasmuch, therefore, as questions continue to reach us every day raising some point or other connected with the Order which is of real importance to those setting up in business for themselves, it will be of service if we review the question again and particularly refer to some of the more debatable cases which have been brought to our notice. Before doing so we may briefly refer to the relation of the Order to photographic businesses.

So far as its connection with photography is concerned the history of the Order is one of muddle. The Order, originally made by the Ministry of National Service in February, 1918, was obviously designed for the protection of men absent on military service. It was intended to protect them from other persons stepping into their places by opening up businesses to replace those which had been compulsorily closed through their owners' absence on service. This was an altogether admirable project, but the surprising thing about it was that for some obscure reason photographic studios were held to be exempt from the application of the Order unless frames and other photographic goods were sold. On the broad question there was no earthly reason why a photographic studio should not have been classed with other retail businesses. It is so classed by the Inland Revenue authorities and under the Shops Act, and a more or less definite inference that it would come under the Order was provided by the mention of the fact that a hairdresser's business is a retail business within the meaning of the Order. Under the Shops Act the business of a hairdresser and a photographer are specifically associated as coming within the Act, and therefore there was a reason for assuming that the same would be the case

under the Retail Businesses (Licensing) Order. Apparently, however, some legal stupidity caused the exemption of photographic studios from the Order, and it was not until August last, as the result of a question in the House of Commons, that photographic studios were brought within its scope. In many towns it was thus a case of shutting the stable door when the horse was gone. Men, at length demobilised from the Army and returning to re-open their businesses, found that others had been allowed to step into their shoes in their absence. Although this decision of the Ministry of Labour, to which the administration of the Order was transferred in May last, provides protection to ex-Service men against businesses started, or proposed to be started, since August last, it is evident that nothing could be done in respect to those businesses which had been opened between February, 1918, and August, 1919, that is, during the unfortunate period of exclusion of studios from the operation of the Order.

As things stand now, anybody, whether British or alien, demobilised or otherwise, who wishes to start a new business requires to obtain a licence for doing so. Apparently the definition of what is a "new" business is by no means clear. The original Order of the Ministry of National Service defined it as one started after February, 1918. The Order, on its re-issue by the Ministry of Labour, defined a new business as one started after May 30, 1919. Nobody seems to know which of these definitions is the correct one. The natural assumption is that the first is correct, since the Order of the Minister of Labour simply amounted to no more than a transfer of executive power from one Ministry to another, but with a culpable lack of common sense in failing to perceive that the definition of a "new" business was entirely altered by the wording of the second Order. Anyone now requiring to start a new retail business needs to apply to one or other of the administrative branches established for carrying out the Order in different parts of the kingdom. We give the list of these branches at the foot of this article, and explain here that in making application for a licence the office selected should be that which deals with the place or district where the business is to be established; the place of residence of the applicant, at the time of making application, is immaterial.

The term "retail business" defines sufficiently well the various kinds of photographic business which come within the scope of the Order. These are, for example, not only regular photographic studios and businesses dealing in photographic requisites, but any kind of photographic business which is carried on with the people resident in a given district. It thus applies to a photographer who makes photographs of people at their houses or secures orders within the district of his place of residence, for the making of enlargements from photographs or for photographing houses, factories or manufactured articles; in other words it applies to all those photographic businesses where the people of the district can buy from or employ a photographer with practically the same readiness as they can buy something at a shop. On the other hand the Order does not apply to businesses which are carried on solely with other trades. For example, a retoucher working for photographers either in the same town where he lives or in other towns does not require a licence, nor does a photographer whose business consists in the developing and printing of plates or films when such business is obtained from other taders in his neighbourhood or even, we think, when it is obtained, e.g., by advertisement, from amateurs scattered throughout the country. This latter case embodies a certain element of doubt. If people living in the neighbourhood of the business could take their plates or films to be finished in the same way that they could buy goods from a local shop, we should say that the administrators of the Order would consider the business one requiring

a licence. Another difficult case is that of a photographer who travels from place to place, taking photographs or groups or canvassing for orders for enlargements. We have no knowledge of how the administrators of the Order are dealing with such cases, but we imagine that under the Order they have power to require a licence from a photographer who plants himself down, say, with a caravan, in a place, carries on a business there in the way of taking and delivering photographs, and then moves on to somewhere else. A licence is supposed to be granted for a business to be carried on at a given place, and therefore it is to be assumed that in theory the travelling photographer would require to have one applying to every place where he makes a halt. On the other hand, there is apparently no power under the Order for restraining a photographer who obtains a licence for carrying on a business at some address from extending his operations within any selected area by canvassing or other means.

The following are the London and provincial headquarters of the administrative staff of the Order, together

with the divisions of England, Scotland and Wales to which they apply:—

- 99, Queen's Gate, South Kensington, S.W.7.—London and South-Eastern (City and Metropolitan Police District, Kent, Surrey, Sussex).
- 5A, Union Street, Bristol.—South-Western (Gloucester, Wilts, Dorset, Somerset, Devon, Cornwall, Hants, Isle of Wight).
- Harewood Barracks, Woodhouse Lane, Leeds.—Yorks and East Midlands (Notts, Yorks (excluding Cleveland), Derby (excluding Glossop and New Mills), Lincoln).
- Queen's College, Paradise Street, Birmingham.—West Midlands (Staffs, Shropshire, Hereford, Worcester, Warwick).
- 80, Westbourne Terrace, Paddington.—South Midlands and Eastern (Norfolk, Suffolk, Cambridge, Oxford, Huntingdon, Bedford, Berks, Bucks, Northants, Leicestershire, Rutland, Herts, Essex).
- New Arts Buildings, Liverpool.—North-Western (Lancashire, Cheshire, Derbyshire (Glossop and New Mills District), Isle of Man).
- 47, Pilgrim Street, Newcastle-on-Tyne.—Northern (Northumberland, Durham, Cumberland, Westmorland, Yorkshire (Cleveland District)).
- 27, Bute Street, Cardiff.—Wales (all Wales and Monmouthshire).
- 15, Athol Crescent, Edinburgh.—Scotland (all Scotland).

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).

 Carbon Printing—II. (Nov. 28).

BROMIDE WRINKLES.

THEORETICALLY, there is no simpler process for producing photographs than bromide printing, but one does not go far in practice before finding out that it is not quite so easy to produce good prints as it looks, quite a number of ways of spoiling paper being open to anyone of average ingenuity. I, therefore, assume that my readers are conversant with the ordinary routine of exposure, development and printing and take up the story where trouble begins.

Dirty margins frequently appear with some workers and rarely with others, showing that the manipulation rather than the material is faulty. Sometimes in the case of a vignette one finds a brownish and grey fog extending half-an-inch or more from the edge and sometimes the entire margin up to the image is more or less degraded. With some papers the stain is of quite a bright orange yellow, and may even extend over what should be white portions of the image itself. This defect

is usually caused by forcing the development of an under-exposed print, and is more likely to occur if the paper is rather stale than when it is quite fresh. It may, as a rule, be avoided by giving a fuller exposure and increasing the amount of bromide in the developer. Great care should be taken to avoid contaminating the developer with hypo: a very small trace of this will cause stains, as witness the yellow corners which frequently appear upon the corners of enlargements which have been pinned up by hypo-contaminated fingers. Those who print in P.O.P. realise what a small trace of hypo will spoil a print, but it is not so generally recognised that the same thing occurs in a lesser degree with bromide paper. It is a curious thing that a large number of people do not see that if the dark-room towel is used to dry fingers dripping with fixing bath the hypo so carried into the fabric will later on contaminate fingers which have been carefully washed. I have repeatedly seen

printers turn over a batch of prints in the fixing bath and dry their fingers on the towel without rinsing them first, then after removing the prints to the washing bath carefully wash their hands, dry them upon the hypo-soaked towel, and start on making more exposures. Fortunately, most stains so caused will yield to the iodine-cyanide reducer, to which I shall presently refer.

A general muddiness or dinginess of the whole print is often caused by using a developer which has become oxidised either by too prolonged use or by allowing development to go on while holding the print in the hand. This is frequently seen when an attempt is made to develop a sky or other light portion of a print locally, the remainder having been slightly rinsed or even left with the exhausted developer upon the surface. Some paper makers recommend transferring the print directly from the developer to the fixer without rinsing. This carries a large quantity of developer into the hypo and dirty-looking prints will result if the hypo bath be not frequently renewed. As a rule, when acid fixing baths are used they are overworked, and many failures in sepia-toning may be traced to this cause, the print when toned appearing to be upon cream paper instead of upon white.

Much may be done to save stained prints by using a clearing solution. I have found none so satisfactory as iodine and cyanide. To make this I keep two stock bottles: one a 5 per cent. solution of iodine in iodide of potassium, and the other a 5 per cent. solution of cyanide of potassium. For use, about ten minims of each are added to an ounce of water, the strength being regulated to suit the work in hand; more of each solution is necessary for deep stains, and less for removing a slight general fog. With practice it is quite easy to effect local reduction by using a pad of cotton-wool dipped in a fairly strong solution. I have often turned a solid print into a vignette in this way, put lights in on clouds in a sky, and even removed portions of the image from the centre of the subject where a clean surface was required for working up. This reducer is the only one, as far as I know, which will act upon a sepia-toned image, but I would recommend that any cleaning-up or reduction should be done before toning, as the untuned image is more readily dissolved.

A print which is flat and heavy-looking all over may be greatly improved by having the lights brightened up with a solution of iodine followed by a plain hypo bath. To do this we take enough water to cover the print, and add to it enough of the 5 per cent. iodine solution to give a sherry colour; on immersing the print the back of the paper will at once turn to a deep blue colour, but the gelatine side will not change colour for a minute or two. When the high-lights turn to the blue colour the print is rinsed and transferred to a 15 per cent. solution of plain hypo; the blue will immediately disappear, and the image will appear brighter. If the reduction be not sufficient after five minutes in the hypo the print may be well washed till free of hypo, and the process repeated. If the iodine solution be too strong there is a tendency for the half-tones to be eaten away and the print made harsh-looking. This method of reduction has been recommended for obtaining bright prints from thin flat negatives, the print being rather over-exposed, fully developed and cleared with the iodine and hypo.

The ordinary ferricyanide and hypo reducer may be used in

the same way as the mixed iodine and cyanide, but there is a possibility of the reduced portions becoming a different colour from the rest of the image, this being specially likely to occur when a weak hypo solution is used. I have found a clean 15 per cent. solution of hypo tinged a full lemon yellow with a 10 per cent. solution of ferricyanide of potassium to give the most satisfactory results.

To obtain good sepia tones, bromide prints must be fully developed, at least a minute's development being necessary, while two or even three minutes are needed for really rich tones. Fixing in clean hypo must be thorough, and all trace of hypo removed by washing. Even a slight trace of hypo will unite with the ferricyanide and reduce a good print to such an extent that it will not darken properly in the sulphide. Weak sulphide solution is a common cause of bad tones. If the paper will stand it without blistering, I prefer a working strength of one part of sulphide in fifty of water, instead of one in a hundred as generally recommended. Prolonged immersion in weak sulphide will not give the same result as a shorter time in a stronger solution. Liver of sulphur, or "potassa sulphurata," as it is called by the chemists, is an excellent one-solution toner with some brands of paper, but it is not suitable for others. In some cases I have been able to get any colour from a warm black through various shades of brown to a warm sepia, but in others I have not been able to get beyond a purple black similar to a deeply-toned P.O.P. The process is very simple, and resembles hypo-alum toning, as the solution is used warm and only a single solution is needed. The formula is: liver of sulphur, 60 grains; water, 15 ozs.; ammonia 10 minims. This is used at a temperature of about 100 degrees Fahr. Some papers will tone without preliminary hardening, but most brands should be treated with a 5 per cent. formaline solution for five minutes, or the film will dissolve. The toning is continuous, and the print may be removed at any stage. It should be noted that the toning continues in the washing, so that the print should be taken out before the desired colour is reached. I have found that much weaker prints may be successfully toned in this solution than by the ordinary sulphide process, but the paper must be suitable.

Rusty coloured prints, which are sometimes inevitable when printing from very hard negatives which must be over-exposed and under-developed, may be greatly improved by toning in an ordinary gold and sulphocyanide bath, as used for P.O.P. The print on being immersed in this will slowly turn to a pure black or grey, and if left in too long to a bluish slate colour. It is desirable to fix in a weak hypo solution after toning to prevent any possible change of colour, but I have found prints not so treated to stand very well.

Another method which I can strongly recommend is to use the ordinary chromium intensifier, which will usually transform a poor, washed-out print into quite a brilliant one. The bleaching bath consists of potassium bichromate, 10 grs.; hydrochloric acid 5 minims; water, 1 oz.; after bleaching, the print is washed until the whites are pure and then re-developed in an ordinary amidol or metol-hydroquinone developer. It is necessary to expose the bleached print to daylight during or after bleaching or the image may refuse to blacken.

PRACTICUS.

THE LATE SILVANUS THOMPSON.—The many admirers in photographic circles of Professor Silvanus Thompson will be interested in noting the announcement that his "Life and Letters," by Jane S. Thompson and Helen G. Thompson, are shortly to be published by Mr. Fisher Unwin. The volume will contain appreciations of his work as physicist, teacher, writer, artist, and "prophet." Professor Thompson was given to expressing his thoughts vigorously, and a representative collection of his letters should make exceptionally interesting reading.

ROYAL PHOTOGRAPHIC SOCIETY.—The annual subscription to the Society may shortly be doubled. At a recent council meeting, on the suggestion of the revenue committee, it was agreed to ask the members at the annual general meeting to alter the articles of association to the effect that members residing within thirty miles of Charing Cross and elected after December 31, 1920, shall pay an annual subscription of £2 2s. Members residing beyond that radius, or elected before that date, to pay £1 1s., as at present, the Fellowship subscription to remain at £2 2s.

A MODIFIED BLEACHER IN CHROMIUM INTENSIFICATION.

THE revival of interest in the "chromium" intensification process evinced by the recent publication in this journal (1) of the preliminary results of a research by MM. Lumière and Seyewetz will be welcomed by those who employ this excellent process. To those who value the quality of permanence, which characterises the chromium intensified image, it is not a little surprising that this process has not completely replaced the many which make use of mercury compounds. The further advantage of being able by a slight modification to use the process for the reduction of excessive contrast in a negative (2) does not seem to have much weight with the average photographer—a truly conservative individual—to whom the only change which is worth serious consideration is one which "makes things easier." It may be safely predicted, therefore, that the chromium intensification process will become the popular process when it is less trouble to work than any other.

Before ideal simplification can be attained, however, much spade work in the form of research has to be carried on, work which adds to the sum of knowledge in other branches of science as well as that with which it is more directly concerned. For example, MM. Lumière and Seyewetz have advanced a tentative theory to account for the operation of the substances used in the process under consideration; should they be able to bring forward sufficient evidence to substantiate their assumptions, fresh light will be thrown on the constitution of chromites and a valuable addition to our knowledge of the chemistry of chromium will have been made.

One of the considerations on which their theory has been enunciated is the fact that chlorochromates are efficient bleachers in this process, whereas no bleaching takes place if the reddish-brown crystals obtained by acting on a bichromate with hydrobromic acid are used. Theoretical considerations would lead one to anticipate such results, for no bromine compounds analogous to the chlorochromates have been prepared. Nevertheless, hydrobromic acid will efficiently replace hydrochloric acid in the bleaching bath. A negative treated with the following solution:—

Potassium bichromate	5 grs.
Hydrobromic acid (25 per cent.)	5 minims.
Water	1 oz. fl.

is effectively bleached, and if after removal of the bichromate stain by washing, the bleached image is developed in the ordinary way a black, strongly intensified image results.

The following points in this modified process are perhaps worthy of mention:—

(a) The bleaching is quite as rapid as that of a bath containing an equivalent amount of hydrochloric acid—in fact, it appears to be somewhat more rapid, but the difference in speed observed may be ascribed to difference in the physical condition of any two negatives rather than to any specific difference in the bleaching bath.

(b) The buff colour of the bleached image is more pronounced when hydrobromic acid is used than when an equivalent of hydrochloric acid is employed.

(c) The amount of intensification appears to be greater in the case of the hydrobromic acid bleaching bath, but the difference in this respect between the two acids is not perhaps sufficient to justify the use of the more expensive hydrobromic acid.

Now, whilst this modification of the chromium intensification process is perhaps of little practical importance, it is worthy

of some attention from the point of view of theory, for it indicates that although a solution of a chlorochromate may be used for intensification purposes, it is not necessary to assume that the chlorochromate *per se* is the active agent, as was suggested by Piper and Carnegie (3). The following alternative theory of the bleaching action is supported by results obtained by the writer, a note of which has been published elsewhere (4).

It is generally assumed that when hydrochloric acid is added in relatively small amounts to aqueous solutions of bichromates an equilibrium is set up by virtue of which chlorine in the nascent condition is obtained. This chlorine may be brought into the ordinary or gaseous condition by the simple expedient of boiling the mixed solution, when something like the following reaction occurs:—

If, however, instead of removing the chlorine by heat, metallic silver be placed in contact with the solutions, the chlorine is removed thereby, and at the same time a chromic salt is produced. When the solution is of the strength which is used in intensification the amount of hydrochloric acid is insufficient for the formation of a normal chromic salt, consequently a hydrated or basic insoluble salt is formed in the film contiguous to or surrounding the silver chloride (5).

An objection to this conception might be urged that, whereas the bleached image is of a brownish hue, the fullness of colour being roughly inversely proportional to the concentration of hydrochloric acid present in the bleaching bath, buff coloured hydrated chromic salts are unknown.

There is no doubt whatever that the buff colour of the bleached image is not contributed by the chromic salt. The writer's experiments already referred to, which were conducted on silver mirrors, and in which analyses of the bath and the "bleached" film were made, clearly demonstrated that chromic acid, CrO_3 , disappeared from the bath and was present as such in the "bleached" film. For reasons which, although affording definite evidence on the point, need not be gone into in the present communication, it may be assumed as highly probable that the basic chromic salt adsorbs chromic acid, and that the buff colour of the bleached image is due to this adsorbed component. Bothamley (6), whilst apparently unaware of the writer's experiments, has offered a similar explanation, but his conclusions are somewhat discounted by the fact that the buff colour is attributed to the presence of chromic chromate—a compound the existence and constitution of which are still subjects of controversy.

Confirmatory evidence of this adsorption phenomenon has since been obtained by the author in a large scale operation in which an oxidation with a bichromate is conducted in a gradually increasing concentration of sulphuric acid. In this case, until the concentration of the sulphuric acid reached a definite minimum, the oxidised insoluble product was contaminated with adsorbed chromic acid, which latter was present in decreasing amounts as the mineral acid content of the oxidising solution increased in concentration above the minimum.

These considerations apart, the theory advanced by MM. Lumière and Seyewetz is somewhat discredited by the constitutional formulæ which are given in support of it. The compound referred to as a double chromite, and which is assumed

(1) "Amateur Photographer," 1904, xl., p. 399.

(2) "Journal Soc. Chem. Ind.," 1916, xxxv., p. 817.

(3) Piper and Carnegie have observed that silver in contact with a solution of chromic chloride is attacked and converted into the chloride with simultaneous formation of a basic chromic salt.

(4) "Photographic Journal," 1918, No. 2, p. 53.

(1) "B.J.," 1919, p. 451.

(2) "B.J.," 1919, p. 465.

to exist as such in contact with a bichromate, has the formula

ascribed to it.

Two objections to this formula may be cited:—

(a) Chromites are generally assumed to be constituted according to the general formula CrO.Om , and no amount of rearrangement will enable MM. Lumière and Seyewetz's formula to be so written.

(b) The electro-positive element silver ($\text{Ag}+$) has departed itself as an electro-negative element having replaced the electro-negative element chlorine ($\text{Cl}-$) of the chlorochromate

Whilst such dual department is well known as a characteristic of many of the elements, there is no known instance of silver so behaving. These are the days, however, of the rough handling of generally accepted theories, and until further work has been done on the question it would be unwise to affirm that the constitution ascribed by MM. Lumière and Seyewetz to the chromium element of the bleached image is an impossible one.

Nevertheless, the efficacy of hydrobromic acid in conjunction with a bichromate may legitimately be regarded, in the writer's opinion, as confirmatory evidence of the views herein reiterated;

for just as the usual bleaching bath may be regarded as a solution containing nascent chlorine, so may a bath made up with hydrobromic acid be regarded as a solution of nascent bromine. This nascent bromine by attacking the silver of the image or mirror, as the case may be, and converting it into silver bromide, is removed from the sphere of action and the reduction of the bichromate to a basic chromic salt becomes a static condition, with ensuing adsorption of chromic acid. The subsequent action of the developer simultaneously reduces the silver bromide to silver and the chromic acid to hydrated chromic oxide, or more probably to chromic hydroxide.

Further experiment should readily decide between the two theories, for the amount of developer consumed in the final development will be appreciably greater for a given amount of original silver in the case of the bleached image being an absorption complex than if the chromium be present in the image in such combination as suggested by MM. Lumière and Seyewetz.

The writer hopes at an early date to be able to continue his experiments the results of which, when taken in conjunction with those of other workers on the subject, may possibly afford positive evidence on the constitution of the compound known as chromic chromate, and should certainly allow of a clearer understanding of the reactions which occur in the chromium intensification process.

RAYMOND E. CROWTHER.

BRIBING THE CHILDREN.

CHILDREN are more susceptible to bribery than anybody else, crooks excepted. We cannot, of course, put children in the same category as crooks, for the good and simple reason that youngsters are totally innocent of any wrongdoing. If it is bribery, it is a commendable and totally inoffensive form of bribery, for it makes the children happy, eases things for their parents and attracts trade.

A merchant in Tupper Lake, N.Y., offered an excellent assortment of cunning, happy dolls with cheerful faces.

The customer ordering £1 worth of photographs during the three weeks set aside for the campaign received one neatly dressed doll 11 to 14 ins. high. If the purchase amounted to £2 the little girl who accompanied her mother was given a medium-size, neatly dressed doll 17 ins. high. If the little girl succeeded in inducing her mother to spend £5 she was rewarded with one large-size, finely dressed doll 20 ins. high.

Charles Mayer and Co., Indianapolis, Ind., made a certain Friday a red letter day for little girls. On this particular Friday morning every girl in Indianapolis who possessed a doll was invited to bring her doll to the studio. There was no distinction between rich girl or poor girl—all had an equal chance—for it was pointed out that it did not matter whether the doll's clothes were torn or faded, or whether the face was chipped or dirty, or the doll big or little, pretty or homely, light or dark, so long as it resembled a doll.

The only rule every little Hoosier girl had to observe was to be sure to pin a piece of paper to the doll with her name and address. On Saturday the dolls were placed in the studio window, and the overflow placed on exhibition in a prominent place inside the studio. Every girl was invited to see the exhibit. On the following Monday a group picture was taken of the dolls. On Tuesday afternoon each girl calling at the studio for the return of her doll was presented with a copy of the doll window picture.

As can be imagined, the stunt got the photographer talked about in

thousands of Indianapolis homes solely by the month-to-mouth publicity of the children. It got every girl's goodwill, and, aside from getting the parents interested in the studio, it must be remembered that the stunt will do the studio good in years to come, when the little girls are grown up and have little girls of their own.

Evans, Indianapolis, Ind., recently ran a series of flags of our Allies in the local newspapers. Half of each advertisement was devoted to a reproduction of a flag and a brief description of it, and the other half was devoted to the photographer.

In the public schools at the present time most of the history and geography lessons are being devoted to the Allies in the Great War. This has resulted in every school teacher availing herself of all the means in her power to inform her pupils more about our Allies. She pounces upon every opportunity to get home the facts as a cat pounces on a mouse, so the photographer who helps her out in this connection is sure to receive her hearty co-operation. Children hate to have knowledge crammed into their systems, but it is surprising how much knowledge they will pick up if there is an inducement connected with it. This Evans realised in inviting the school children to cut out the advertisements, which appeared every Tuesday and Saturday. The children were then told to colour the flags with crayon or paint and they would soon have a full collection of the flags of the Allies. This stunt might be improved upon by offering prizes for the best coloured flags.

A photographer in Chattanooga, Tenn., knowing how children worship their war idols, offered a photograph, size 15 by 18 ins. of President Wilson or General Pershing with every 10s. order.

It will always pay the photographer to take the child into consideration, for the child will be grown up some day. If a favourable opinion is formed of a photographer while the child is in the impressionable age, it will remain long after she is old enough to utilise her own judgment of things.

ERNEST A. DENCH.

FORTHCOMING EXHIBITIONS.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Sec.: John Macdonald, 27, Aberfeldy Street, Dennytown, Glasgow.

THE SCIENTIFIC AND TECHNICAL GROUP of the Royal Photographic Society will hold its first annual general meeting at 35, Russell Square, on Wednesday, December 17, at 7 p.m. The meeting will

be preceded at 6.30 p.m. by an informal gathering of members of the Group in the library, and it is hoped that as many as possible will be present on this occasion. Since the circular setting forth the activities and membership of the Group was published some twenty-five further members of the society have applied for admission, and it is therefore expected that the membership of the Group will reach a total of about 200 early in the new year.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Reducing-out Backgrounds.

IN many copies and some commercial subjects it is preferable to remove the detail in the background so as to permit the latter to print black rather than to block out the negative with opaque paint in the usual way. Some years ago I worked out a method of doing this by coating the film side of the negative with collodion and using a very strong iodine solution, applied by means of a brush, as the reducing agent. This was published in the "B.J.," and although it was preferable to scraping the film, especially in the case of negatives for enlarging, it was not an ideal method, and the following procedure will be found to be an improvement upon it.

The negative is first to be thoroughly dried by heat or otherwise, and as soon as it is cool it is coated with collodion just as in the previous method. The coating, however, need not be all over the film so long as the whole of the subject itself is covered. If collodion is not at hand probably almost any other kind of waterproof varnish could be used, but I have not tried any other. When the collodion is dry a little fish-glué (Secotine) is thinned out with a drop of water, to which a trace of dye or pigment is added. With a sable the edges of the subject are painted over with the mixture in a retouching desk, the colouring matter making it an easy matter to see whether any part has been omitted. Then the plate is laid flat, and the subject filled in with a larger brush so that the whole of the figure to be retained is covered with fish-glué. As soon as this is dry, which may be hastened by warmth, the plate is mopped over with a mixture of equal parts of ether and alcohol to dissolve away the collodion from the background. If another kind of varnish has been employed naturally its appropriate solvent should be applied at this stage. The coating of fish-glué over the subject will act as a resist against the solvent, and so will prevent the varnish underneath it from being dissolved. The latter in its turn acts as a resist against the reducing solution, which is preferably applied with a mop of cotton-wool, as total immersion may find weak spots in the varnish. As soon as the background is reduced out, the plate is rinsed and mopped surface-dry, and the rest of the varnish dissolved. Then a good wash completes the process. In portraits it will be found an improvement to reduce the edges of the subject slightly after removal of the varnish, so as to avoid a cut-out appearance. This may be still further modified by pencil work, as the film is not injured in any way, and may be retouched as usual. —D. CHARLES.

Finishing Blocked-out Negatives.

MANY suggestions have been passed round for covering the portions of the background left uncovered after the outline of a subject has been done with opaque. To cover the whole with opaque is wasteful and not always effective, the paint being liable to abrasion in large areas. A paper mask is the most practical, but a P.O.P. proof nowadays is costly, and a black paper mask not easy to get even an approximately correct shape upon. The following has been found a remarkably quick and easy plan. When the outline band of paint is dry, the negative is laid flat on a table in a good light, and a brush well charged with the paint is drawn round just overlapping the line already made, making it about half-an-inch wide and rounding out any awkward corners. As soon as this is dry again the negative is laid film downwards, this time on a printing box, and a few spots of secotine put on the glass side in the corners and other convenient positions, but not over the subject itself. These spots are rubbed out thin and smooth with a finger-end till they become tacky, when a sheet of translucent red paper is laid down upon the glass. It is then a matter of an instant to run the point of a sharp knife around the subject, cutting through the paper. The subject can be seen, and the band of opaque gives plenty of latitude, so that there is no particular line to cut to. Thus a correct mask is made in a few seconds, and is already fixed to the negative. A suitable paper is obtainable from Messrs. Butchers.—K.

A Printing-Box Dodge.

ABOUT an inch below the plate-glass top of my printing-box is a shelf consisting of a sheet of ground-glass supported on a slat at each side. A slit in the box itself allows "vignettes" or "tissues" to be slid on this shelf at a suitable distance beneath the negative.

Finding it rather difficult to adjust the positions of pieces of tissue paper, for keeping back thin parts of negatives, without frequent lifting of the top of the printing-box, I have hit on the following dodge, which answers splendidly, as well as giving a practical method of damping down the light for weak negatives. Some tracing-cloth was obtained, and pieces were cut the width of the glass shelf and a little more than twice as long. Each piece was folded once, and the two edges opposite the fold pasted together to form a folder closed back and front and open at the sides. A metal ring was attached to each at the same time at one corner by narrow strips of the tracing cloth. One strip passed through the ring, and the ends with plenty of adhesive put between the two pasted edges of the sheet. Then another small pasted strip was passed through the ring, and stuck outside the folder, making, when dry, a quite untearable means of hanging the folders up when not in use.

I find three of these fill all possible requirements for regulating the strength of the light. When a negative needs dodging, it is laid on the box and one of the folders placed on top of it. Then the bits of tissue paper are slipped inside the folder, and when adjusted to the negative the whole is slid as one piece on the glass shelf below, without further trouble.—K.

A Lens-cleaning Hint.

THE advice to keep a special piece of chamois leather or o'd linen for cleaning lenses is excellent, but often is carried out in practice in a manner worse than useless, by the habit of keeping the cleaning material loose in the camera case, or lying about in a drawer or on a shelf where it picks up all sorts of grit. Frequent polishing then results in a beautiful cross-hatching of fine lines over the surface of the soft glass of which a lens may consist.

The method I have adopted is to have a chamois leather bag, and to use the *inside* of this only for wiping lenses. Thus the surface that does the work is always free from dust and dirt. For the benefit of those who work in the West-End of London, I may mention that a woman stands around Covent Garden market selling such bags, presumably as purses, for a few pence each, and these are strung with tape which forms a loop by which the bag hangs on a nail always handy when needed. I have been fortunate in buying a specially smooth white one from her of a softness not met with before.

When a chamois needs washing, it is easy to retain the softness. A thick lather of soap and warm water is used, "Lux" being quick and suitable for the purpose. The leather is rubbed out in the lather, squeezed, and hung up to dry *without rinsing*.—K.

FIXING IN THIRTY SECONDS.—At a meeting of the Royal College of Science Chemical Society on Friday last, November 28, at South Kensington, Mr. K. Hickman gave a lecture on "Photographic Pastimes from the Chemist's Viewpoint."

The lecturer (as reported in the "Times") opened with a demonstration in flashlight photography. A "snap" of the audience was taken, and also a photograph of the chairman. The plates were then given a rapid development with a lightning wash; fixation in a fixing solution, effective in thirty seconds, recently discovered by the lecturer; a further washing for two minutes, in which time the hypo was removed by dilute permanganate; a bath for two minutes in formaline solution, after which the plate was rinsed, dried in a stream of hot air from a machine of the lecturer's design; and finally printed on a lantern plate. Thus, within half an hour of the exposure a lantern slide photograph of the chairman was projected on to the screen.

Later, Mr. Hickman dealt with the screen-plate method of colour photography, which, he said, by its simplicity and the beauty of its productions had ousted all other methods for amateur work. The lecturer screened many examples of slides taken by the Paget process, including flower and scenic studies and portraits.

Exhibitions.

MR. SPEAIGHT'S PHOTOGRAPHS OF SPITSBERGEN.

It would be a very partial appreciation of the photographs now being shown at the Speaight Galleries, 157, New Bond Street, to say that they are a very pleasant collection of examples of Mr. Richard N. Speaight's art in the field of landscape photography. They are certainly that, and so serve usefully to demonstrate that a photographer who has spent the greater part of his life in the study of tone values as they occur in portraiture is able to make excellent use of his self-training when he goes out of doors for his subjects. But the collection, or, perhaps, rather the exhibition of it, possesses more than ordinary interest from the fact of its marking a new kind of enterprise on the part of the West-end photographer. Spitsbergen, for all we know, may be a nice enough place for a holiday trip, but it is as a commercial entrepreneur rather than a holiday-maker that Mr. Speaight offers his photographs for the inspection of the public. The commercial interests which are thus forwarded are those of the Northern Exploration Co., Ltd., the joint-stock undertaking which holds large rights for the getting of coal, asbestos, iron ore, marble and other minerals from the rich deposits on the island of Spitsbergen. The little exhibition serves to bring before a wealthy public the prospects which are offered to the company holding these rights, and does so in the unostentatious semi-detached style of advertisement of which the firm of Messrs. Speaight, Ltd., are past masters. For the rest it can scarcely be said that the photographs realise the glowing epithets applied to the Spitsbergen landscape in a preface to the exhibition catalogue by Dr. R. Cathcart Bruce. For adequate rendering of the "brilliant natural colouring" Mr. Speaight's exhibition should surely have been one of Autochromes or at least photographs from panchromatic negatives. Apparently a Spitsbergen moss-landscape loses a good deal of its natural beauty when rendered in unassisted monochrome.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- Applications November 17 to 22.
- PRINTING PAPER.—No. 28,714. Photographic printing paper. Kerotype, Ltd., and T. P. Middleton.
- PRINTING AND TRANSFER PAPER.—No. 28,980. Photographic printing paper and transfer processes. Kerotype, Ltd., T. P. Middleton, and T. A. Mills.
- X-RAY PHOTOGRAPHY.—No. 28,566. Manufacture of photographic plates, films, papers, etc., for X-ray photography, etc. J. C. Mottram.
- PHOTOGRAPHIC APPARATUS.—No. 28,498. Photographic apparatus. J. P. Hansen.
- CINEMATOGRAPHY.—No. 29,109. Cinematograph projection apparatus. N. E. Barber.
- CINEMATOGRAPHY.—No. 29,131. Cinematograph film guiding devices. P. H. Bastie.
- CINEMATOGRAPHY.—No. 28,440. Cinematograph apparatus. H. Maler.
- CINEMATOGRAPHY.—No. 29,051.—Cinematograph film joints and process and apparatus for manufacture thereof. J. E. Thornton.
- CINEMATOGRAPHY.—No. 29,146. Safety shutters for cinematograph projection. W. Willmann.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SCREEN PLATES FOR COLOUR PHOTOGRAPHY.—No. 129,717 (December 7, 1917). The invention consists in a method of making mosaic colour screen plates of a degree of fineness suitable for cinemato-

graph films. Particulars of the process are given on another page of this issue in the "Colour Photography" Supplement. There are sixteen separate claims made in respect to the invention, all dependent on the first, which is as follows:—Forming a discriminative composite colour-screen suited to determine the production of and control the viewing of a photographic monochrome in the well-known manner on a base which is non-absorbent for aqueous preparations, but is generally absorbent for alcoholic and aromatic preparations, as, for example, a base of simple or compound cellulose ester, by laying on this base colloid lines or areas with a fluid aqueous coloured colloid preparation as described, then, after drying, staining the base by a solution of a dye in a fluid which the base absorbs; the colour of the stain being broadly or generally "antichromatic" to the colour in the aqueous colloid.—Joseph Thomas Smith, St. Peters-upon-Cornhill, London, E.C.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 2, Mr. W. B. Ferguson, K.C., in the chair.

Mr. A. H. Lisett gave a demonstration of lantern-slide making, in the course of which he very fully described his own practice. The treasurer of the Society is a man of system, whose sense of order is offended by anything which savours of the haphazard. Thus much of the advice which he inculcated was concerned with rules and expedients by which failure due to errors of judgment might be eliminated. He showed how allowance could be made for the various factors affecting exposure in lantern-slide making, such as density and colour of the negatives, and working aperture of lens when making slides by reduction. An important part of

his procedure consisted in notes made of slides produced under previous known conditions. While it may be doubted whether the average maker of lantern-slides can be persuaded to work in an equally systematic way, it must be admitted that from the many results which he showed upon the screen Mr. Lisett could point with ample justification to the exceedingly fine quality of his work.

The Chairman, in dissenting from the recommendation of time development in lantern-slide making, pointed out that while the system was all right for negatives, where it did not matter if density varied, in the case of lantern-slides it was bad practice. He knew of no way of working except by examining the transparency.

GROYDON CAMERA CLUB.

A WELCOME evening for the beginner was afforded last week by the popular president, Mr. John Keane, giving a plain demonstration, "How to Make Bromide Enlargements with the Club Lantern." At first sight this may seem a simple proposition, but the utilisation of the club lantern, which, like a fried mutton chop, is generally regarded by epicureans as the last refuge of the destitute, indicates the president has nerve unimpaired after nearly two years' reign over a turbulent tribe.

Naturally his best friends fondly hoped he would come some sort of a cropper, such as exposing on the wrong side of the paper, or mistaking hypo solution for developer, etc., but the only desirable step in this direction consisted in his forgetting to add the amidol to the sulphite solution, which delayed appreciably the appearance of the image.

It is not necessary to follow Mr. Keane through an admirably delivered elementary exposition, from which good advice flowed in a continual stream. This, of course, kept the demonstrator in the best of spirits, and as it was never seriously at variance with preconceived notions its recipients were equally happy. He invariably employs the "Welborne Piper" formula for an amidol developer. This was stated to be as follows:—Soda sulphite crystals, 2 ozs.; metabisulphite of potash, $\frac{1}{2}$ oz.; water, 10 ozs. For use, take 1 oz. of the stock solution, 2 ozs. water, and 6 grs. of amidol. "Develop to the bitter end," he said, a recommendation which many considered appropriate to the enlargement subsequently produced, technically first-rate and in mildly decorative vein.

As a matter of fact, and it was so pointed out in the discussion, Mr. Piper later modified the original formula by halving the metabisulphite, as being the best proportions for neutralising average samples of sulphite, consequently Mr. Keane was probably employing a distinctly acid solution, which may have accounted for the abnormally long time the print took to develop. He said he had never been let down with his formula, but others narrated contrary experiences, and pointed out that as the addition of the acid salt was primarily intended as a preventive of oxidation, the safest course was to make up fresh sulphite solution each time as generally recommended by the makers of bromide papers.

Mr. Vivian Jobling put in a good word for the hydroquinone-metol developer, which in his hands had kept remarkably well. Mr. E. A. Salt doubted whether any of the modern developers gave better blacks than the old iron developer. Mr. H. P. C. Harpur agreed: the iron developer was more troublesome, and risk of failure was increased, but the intense blacks it rendered had, to say the least, never been beaten.

Towards the end of the demonstration Mr. Keane, who had been doing a lot of plain talking, expanded somewhat. "Well, gentlemen," he declaimed, "after having exposed our bromide paper, developed, fixed, washed and dried the print, what then are we to do?" "Put it in the dustbin," promptly replied a member with deadened artistic soul. The answer sufficed.

It is with great regret that we have to announce the death, at the age of seventy-nine, of Mr. John Nooks, an old and highly esteemed member of the club. Right royally he worked for it in days gone by, and he will be sadly missed by many friends. Exhibition work had little attraction for him, but he was ever a sound photographer, with a good eye for the beautiful. In later years he took up the Autochrome process with enthusiasm, and achieved remarkable success.

Commercial & Legal Intelligence.

THE ILFORD DIVIDEND.—For the year ending October 31 last, the directors of Ilford, Ltd., have recommended a dividend of 8 per cent. on the ordinary shares, against 6 per cent. a year ago.

AT THE LONDON BANKRUPTCY COURT on Wednesday in last week, before Mr. Registrar Hope, the public examination was appointed to be held of Richard Cardwell Barron, photographer, 7, Queen's Street, Bloomsbury, W.C., lately trading at 19, Cheapside, E.C., and lately residing at Shedfield, Ashley Road, Thames Ditton, against whom a receiving order was made on October 14 last, on the petition of a creditor, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice.

Upon the case being called on for hearing, the Official Receiver stated that debtor had only filed his statement of affairs on the previous day, and the usual summary had not been sent out to all creditors, therefore he asked that the examination might be adjourned in order that he might have time to go into the matter.

The learned Registrar accordingly adjourned the examination until January 21.

Subsequently an official of the Court stated that debtor was in attendance, and was willing to be examined, but the Registrar said that as he had only just filed his statement of affairs it was impossible to go on with the examination that day, because the Official Receiver must have time to investigate the matter.

LEGAL NOTICES.—At an extraordinary general meeting of the Sketch Photo Company, Limited, held at 10, Leigham Terrace, Plymouth, the following resolution was passed, and at a subsequent meeting was duly confirmed: "That the company be wound up voluntarily, and that Mr. E. R. Bowden, certified accountant, 11, Athenaeum Terrace, Plymouth, be appointed liquidator." Creditors of the company are required to send on or before December 21 particulars of their claims to Mr. E. R. Bowden, above address.

Notice is given of the dissolution of the partnership between Percie C. Cooper, Algernon M. Cooper, and H. de Horne Cooper, carrying on business as photographers, photo-mechanical printers, etc., Cranfield Works, Cranfield Road, Brockley, under the style of the Cranfield Press, so far as concerns Algernon Morris Cooper, who retires. All debts due to and owing by the late firm will be received and paid respectively by Harry de Horne Cooper and Percie Cyril Cooper, who will continue to carry on the business under the style of Alfred H. Cooper and Sons.

NEW COMPANIES.

RAJAR, LIMITED (private company), was registered on November 24, with a capital of £300,000 in £1 shares. The objects are to take over the business of Rajar, Limited (incorporated in 1907), and to carry on the business of manufacturers of and dealers in photographic materials and apparatus, advertising specialties and novelties, showcards and almanacs, chemicals, etc. The first directors are:—A. E. Parker, Wadhurst, Sussex, paper maker (director of Wiggins, Teape and Company, 1919, Limited, and Rotary Photographic Company, 1917, Limited); T. L. Parker, Withnell Fold, Chorley, Lancs., paper-maker (director of Wiggins, Teape and Company, 1919, Limited); C. F. S. Rothwell, Thornedge, Spring Road, Hale, Ches., chemist (managing director of Rotary Photographic Company, 1917, Limited, and director of Lilywhite, Limited). Registered office: Rajar Works, Town Lane, Moberley, Ches.

PRESS SERVICES, LIMITED.—This private company was registered on November 25 with a capital of £500 in £1 shares. Objects: To take over the business of a Press and commercial photographic service now or recently carried on by H. F. Baldwin at 47, Fleet Street, E.C., as the "Baldwin Photographic Press Service." The subscribers are:—W. G. Gilbert, 12, Harders Road, Peckham, S.E.15, engineer, 300 shares; R. E. Norman, 21, Marmion Road, North Side, Clapham Common, S.W., press photographer, 100 shares; H. F. Roberts, 54, Ivy Road, Cricklewood, N.W.2, engineer, 100 shares. Permanent directors: W. G. Gilbert, H. F. Roberts, and R. E. Norman (manager and secretary). Qualification, £10. Secretary: R. E. Norman. Registered office: 47, Fleet Street, E.C.

News and Notes.

MESSRS. WALLACE HEATON, LIMITED, 17-19, Change Alley, Shetfield, send us a 40-page illustrated price-list of second-hand apparatus just issued by them. In addition to describing many popular patterns of camera and other photographic apparatus, it contains sections specifying bargains in microscopes and field glasses.

A WAR MEMORIAL BOOKLET showing the part taken by the town of Leiston, Suffolk, in the war has been produced and issued by Mr. J. S. Waddell, The Hayling Studio, Leiston. It briefly details the achievements of Suffolk regiments in France, the local contributions to munition making, and the work carried on in the way of food production and coastal defence in a district which was constantly exposed to the threats of enemy bombardment or invasion. Several large mosaic photographs have as their subjects the many men in Leiston and the surrounding districts who have fallen in the war. The price of the booklet is two shillings.

EXPRESSION OF THE EYES.—Writing to "Camera Craft," a contributor comments upon the strained expression obtained in the eyes by asking a sitter to look, or fix the eyes, on a certain spot. A very much more pleasing expression is obtained by getting the sitter to look at a group of pictures on the wall. Perhaps the eye will roll just a little, but the motion will be so slight as to be unnoticeable. It would appear that the travel of the eyes which is encouraged by the group of pictures results in a slightly wider-open effect, certainly a less strained one, which is most desirable. In addition, the larger number of pictures is more interesting than the single one, and this also conduces to a less constrained look. The writer suggests that those who will take the trouble to make a few comparative exposures by this method alongside that of sliding a picture up and down on a rod will speedily convince themselves of the benefit which it brings as regards a pleasing and natural expression in the eyes.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen.—Of the recent correspondence on the subject of the formation of a union of assistants, the nearest solution seems to be that of the Photographic section of the N.A.U.S.A.W. and C., as put forward by Mr. Harry G. Ward in your issue of the 21st ult.

It seems to me that it fulfils all the suggestions by your correspondent "Another Hopeful," as this society has already headquarters in London and branches in all the principal provincial towns, so that it would be quite easy for assistants out of London to meet together.

We should have the advantage of having a powerful organisation behind us to commence with, and also the help and experience of officials who are men already trained and accustomed to deal in matters affecting questions of labour.

The previous attempts to form a union of assistants have failed chiefly, I honestly believe, owing to the desire of so many to wait and see the other chap make a start, but assistants must shake off this spirit, and each one must get a move on.

I have joined the N.A.U.S.A.W. and C. myself, also induced a colleague to do the same, and hope to persuade several others; and if every assistant would only do likewise, then at last we should be on the road to success.

The future of the assistant depends upon organisation. If the employer can obtain labour for less than a living wage, who can blame the employer?—Yours faithfully,

"FORWARD."

To the Editors.

Gentlemen.—Some of your correspondents compare the position of the worker in photography with that of those in other trades; but photography is widely different even from other luxury trades. Before we can hope to improve our position we must at least understand it.

Modern wage increases have little to do with comparative skill. They depend upon the power of closely compacted labour—in mines and factories, for instance—to resist its own dilution, and, further, the power to bring economic pressure on the employer or on the public generally, as in the recent railway strikes.

Presuming that every adult assistant was unionised, could we control the dilution of our own labour? With thousands of scattered businesses up and down the country, each the channel in one way or another of an over-generous flow of boy and girl labour into the trade, the answer is most emphatically No!

As regards economic pressure? It is possible for most of the good old British public to go from the cradle to the grave without worrying a little bit about photography. They have to be coaxed. Any necessitous work could generally be carried through in some fashion by the average employer because he is usually his own principal assistant. Of most of them you can say that they haven't time enough to be managers or money enough to be capitalists. Any necessitous work that the employers couldn't do would be attempted at a cheaper price by hosts of back-garden amateurs. Such, gentlemen, is our ignoble profession. Can and will nothing ever be done? Nothing, until photography is frankly recognised as a sweated, uneconomic trade, and a trade board appointed, as in other similar trades, to improve wages, hours, and conditions, and to settle admission, training, and generally level things up a bit.

The tailoring sweat-shop is a thing of the past; but the type of humanity that used to run them is fast coming into photography, alive to the possibilities of multiple shops, worked at high pressure with a factory behind them. He always opens Sundays. He would open night and day if he thought that there was money in it. The pride and self-respect of the craftsman is nothing to him. It is for reputable photographers, employees and employers alike, to decide whether they will hang together or hang singly.

In "process" work the employers' federation fixes minimum prices. The employees' union has secured a minimum standard wage of £4 7s. 6d. for work that is certainly not more exacting than that of the average photographic assistant. But "process" has the advantage of being associated with the always highly organised printing crafts. It is a compacted trade. Straight photography is not. Much time and effort has been wasted in the past on ambitious photographic union schemes. The one essential thing for the moment is just a trade board. Would assistants be prepared simply to sign a petition for one if forms were circulated?

What is the feeling of assistants of both sexes with regard to action on these lines?

If the "B.J." would oblige by giving this idea publicity, and opinion seems generally favourable, it will be a simple matter for some of us to get together and make a start.—Yours truly,

DIGGER.

NEGATIVE BROMOILS.

To the Editors.

Gentlemen.—A statement by Mr. Clifton in the report of the demonstration he gave at the Croydon Camera Club, as reported in the "Journal" of November 21, to the effect that he had never met with negative Bromoils in pre-war days is quite contrary to my experience.

Up to 1914 I suppose I made some hundred or more Bromoils each year, and certainly found 10 per cent. pigmented up as negatives. The late Mr. Welborne Piper wrote to me on the process when he first discovered it, and this phenomenon had already appeared. He was unable to explain it; we made some tentative experiments, but the pressure of my professional work prevented me following them up, and I think other more important matters absorbed his attention.

He generally used ordinary picture postcards for his experimental work, and I, prints made on all the well-known bromide papers, including those mentioned by Mr. Clifton. The negative appearance was met with on all, but we never knew when to expect it. By the way, it was not new to me, as it had occurred also when I worked the Rawlins oil process (see "Oil and Bromoil").

The best remedy is to soak the print in water, clean all the pigment off with petrol or carbons, dry the print, then start *de novo* another day. By continued pigmentsing the negative may be converted into a positive, but the result is not so satisfactory as when the former plan is adopted.—Yours faithfully,

Parkstone, Dorset.

A. R. F. EVERSHED.

QUANTITY TANK DEVELOPMENT.

To the Editors.

Gentlemen,—May I trespass on your space to reply to Mr. England's criticism of my notes on Tank Development? I was not thinking of the cheapest class of work, but of those middle-class studios where four or even six negatives are made of each sitter and proofs sent of three or four. Working on these lines, Mr. England will find it quite possible to expose 160 plates in a day, although it is admittedly rush work. With regard to re-touching and printing, any trade worker will tell you that in the busy season many businesses do put out all this work.

To take Mr. England's second point, I hoped and thought I had made it clear that I was advocating tanks simply for their greater holding capacity, not with a view to time development. Working on these lines, the developer may be absolutely the same as for dish development. For time development, of course, a weaker solution is much better.

Mr. England suggests that assistants should be employed. The trouble is that the rush will not last for more than a few weeks, after which the number of sitters will drop to perhaps three a day. I suppose that the assistants will then have to find other jobs! There are already far too many of these temporary jobs about.

If Mr. England will glance at the last paragraph of my notes he will see that I was not thinking only of one-man businesses. As a matter of fact, it was as an assistant that I experienced this sort of work, and it was my desire to show how the working conditions of such assistants might be improved. Perhaps the choice of a one-man business to illustrate my point was an unfortunate one.

Yours faithfully,

ARTHUR G. WILLIS.

Alton, Hants.

WAR WORK OF THE EASTMAN RESEARCH LABORATORY.

To the Editors.

Gentlemen,—Your surmise in the issue of October 10 that the smaller number of communications published recently from our research laboratory has been due to the diversion of our activities to war problems is correct in the main. It may interest you to know what the chief war activities of the laboratory were.

The physics department under the charge of Mr. L. A. Jones, who was given a commission as lieutenant in the United States Navy, was devoted to the investigation of marine camouflage, the laboratory research on this subject being conducted at Rochester. Dr. S. E. Sheppard, in the physical chemical laboratory, took up the study of colloidal fuel, and succeeded in preparing a substitute for fuel oil containing 30 per cent of pulverised coal, this fuel showing a very considerable economy as compared with the use of standard fuel oil. The photographic division of the laboratory with the section of photographic physics was devoted to aerial photography, the two main branches of work in this field being the organisation and supply of instructors for the school of aerial photography at Kodak Park, where the ground photographers for the United States Army were trained, and the laboratory investigation of the theory of aerial photography. This latter investigation is now being prepared for publication in the form of a monograph.

In the latter part of 1918 almost all the work of the laboratory was directly connected with military work, and none of its regular work could be carried on. This is not the sole cause for the lessening of publication at the present time, however. When we resumed our work after the Armistice was signed, we found that a great deal of the fundamental research work which had been done had accumulated beyond the possibility of publication in the form of

papers. Many of the researches would have required space for publication which no journal could be expected to supply, and it was consequently determined to adopt another form of publication and to prepare a series of monographs dealing with the theory of photography. During the present year these monographs have been started, and three are now well advanced in their preparation, while others have been commenced. While continuing the publication of our work in the form of communications, we hope, therefore, in future to collect work in each special field of photographic theory in this series of monographs, the first members of which will probably be published in the early part of 1920.—Very truly yours,

C. E. K. MEES.

Eastman Kodak Company, Rochester, N.Y.,

November 11, 1919.

MOUNTING BLOCKS TO POINT MEASURES.

To the Editors.

Gentlemen,—May I have a few lines in which to reply to "Bronze Medallist," of the Manchester School of Technology, for the contents of the letter leads one to the supposition that he is very superficially acquainted with the subject, otherwise he would not write so loosely as he does?

Were he a process engraver he should be much more cognisant of the facts and difficulties of the subject than his letter would lead one to believe him to be. Perhaps it is that as our "Bronze Medal" dates back nine years he has not kept himself fully informed on process matters since that date.

He lays it down that the "jobbing printer is more anxious than ever that the . . . point system be applied" by the engravers, and states it not merely as an opinion, but as though it were a fact, but he gives no evidence in proof of his assertion.

As a practical process block-maker, I assert that if the fault lies anywhere it lies at the door of the printer himself, because he will not order his blocks by point measurement, especially if such extreme accuracy costs him a veritable fraction more than the lowest price at which he can purchase his blocks without such accuracy.

The excuses your correspondent puts into the mouth of the process engraver are mere nonsense, and his assertion that it is as simple to mount a block to point measurement as to mount it type high is only equalled by his other assertion that this portion of the work is "relegated to unskilled and semi-skilled labour." If he knows anything about the trade at all, after his thirty years' experience, he should know that such a statement will not bear investigation.

I quite agree that the system "would confer a boon," and that the "extra cost would be worth paying for by the printer"; but will he pay it? And will it "bring the block-maker more business for himself"?

Here are a few facts. I am a staunch believer in the point system, and a more staunch believer in sending out blocks perfectly true in every way, so at great expense to my firm I launched a campaign on the printing trade. I sent several communications to practically every printer of any repute in this country offering them their plates mounted on a patent mount, *guaranteed* true to point measurement and type high, dead true in every way, and all this *guaranteed*. But, alas, to receive this cost the printers one half-penny per square inch more than the usual cost of his blocks. What was the result—absolute failure, for out of the less than 100 replies we received (from printers only, remember) about 80 or 90 per cent. persisted in ordering by inch measurements, and some 60 or 70 per cent. thought the *½d.* per square inch too great a price to pay for the accuracy. So after many months' struggle to introduce point measurement and dead accurate work we gave it up as a bad business, and to-day our experience is that not one-tenth of 1 per cent. of the orders that come to us from printers are ordered by points instead of inches.

If your correspondent considers it "time the block-makers got a move on," and that it seems a simple matter to devise means whereby blocks can be turned out dead true to point measures "automatically as easily as the present system," let him by all means get to work and show us how. I for one will give his system a hearty welcome, even though it might turn out that theory and practice did not agree.—Yours truly,

TH. EAMES,

Managing Director of the Marshall Engraving Co.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

T. W.—You require a licence, the office for which is at Queen's College, Paradise Street, Birmingham. There is no charge for the licence, and it holds goods as long as the Licensing Order remains in force.

G. T.—Apart from the copper toning process, which is not now in much favour, the only formula we know is that of sulphide-toning in the usual way, and then toning the sulphide-toned prints in a gold sulphocyanide bath as used for P.O.P.

N. AND Co.—The two firms for enamels are Mr. J. W. Beaufort, The Studio, Easy Row, Birmingham, and Farquhar Vitrified Enamels Co., Derby Lodge, East Sheen. There is no other form of photograph which could be used with the certainty of it withstanding prolonged exposure to weather.

C. R.—The office of the Retail Businesses (Licensing) Order to which you should apply is at Queen's College, Paradise Street, Birmingham. We do not think you can be restrained from canvassing outside your own town so long as the business proper is carried on at the address in respect of which the licence is issued.

W. N.—Dissolving views are almost completely out of favour with the general public. You had very much better spend the money on the best equipment in the way of light for a single lamp. We assume, of course, that you are intending to show ordinary photographic slides, not dissolving-view effects such as had some popularity twenty or thirty years ago, but now, except for children's entertainments, are utterly out of date.

G. H.—The chief consideration is not the size but the design of the burner—that is, the proper adjustment of the gas passages and air inlet. By far the best burner that we know of is the inverted "Howellite," which Messrs. Griffins supply. Your lens is all right, supposing that it has a focal length of at least 8 ins.; all the better if 9 ins. With this lens and a good incandescent light you ought to be able to enlarge 5 to 6 diameters without exposures becoming inconveniently long.

C. E. G.—We are quite at a loss to account for the stains on the enlargement from the particulars you give. If we had nothing whatever to go upon, we should have said that the enlargement had been wilfully dabbed over with some bleaching solution, such as ferricyanide and bromide, as used for sepia toning. The paper appears to be one by a leading maker, and therefore we think it is a matter which might reasonably be referred to the makers, so we return the enlargement.

E. K.—There is no means that we know of taking out the stains. If it is a very light-coloured fabric, some benefit no doubt could be made by rubbing the stains with a little paste made of bleaching powder (chloride of lime) to which a very little hydrochloric acid has been added—enough to give the mixture a chlorous smell. This will attack developer stain, but, unfortunately, also the dye used for most dark fabrics. If it is a dark suit, about the best thing you can do is to make the stains less conspicuous with ordinary ink.

M. B.—1. You tell us so little about the stains that we can only guess at the cause. If they occur with large numbers of prints, and all in places near to the edges of the cards, it is just possible that they may be due to a defect of manufacture, although we have never seen anything of this kind. Still, failing this explanation, we can only suggest that they are due to some chemical contamination such as hypo or sulphide before or during development. 2. You can get a cement for sticking celluloid to negatives from Messrs. Rheinlander, New Malden, Surrey.

W. E.—Very likely painting with quinine has been mentioned by various people from time to time, but it is a relic of the wet-collodion days. No doubt the process you suggest would work if wet-collodion plates were the only sensitive material available. But it does not do with dry-plates, which in the ordinary way show no sign of the invisible quinine markings. We know of no secret writing which can be done so as to defeat the copyist. We are afraid the only course of this kind which you can take in self-protection is to deface the prints with ink, say from a rubber stamp, or by perforating them with your trade name, as is commonly done by photographers when sending out proofs.

C. L.—1. Prices range from £3 to £10, according to lens. 2. We have not a price list of the plates and brooches. You should apply to Fallowfields, 146, Charing Cross Road, W.C.2, or to Messrs. Moore and Co., 103, Dale Street, Liverpool, who are makers of the cameras. 3. Yes; developed and fixed at one operation. 4. Rinsing in water for three or four minutes. 5. As a rule, not more than about $f/8$. 6. Yes, most of the cameras are of fixed-focus type. 7. If you have been in the photographic business at your present address prior to February, 1918, it would not be necessary to obtain a licence. If your business has been established since that date, you presumably have obtained a licence, the office for which is Harewood Barracks, Leeds. The only other permit that may be necessary is one from the police. Police authorities in different districts differ considerably in asking for this.

H. B.—Unless you are working from negatives which have a lot of retouching on them, by far the best electric enlarging light is a small arc lamp such as that of the Westminster Engineering Co., Victoria Road, Willesden Junction, N.W. However, the arrangement of diffused light which you suggest is quite practicable, and is in fact used to a fair extent by professional photographers, as it is better for retouched negatives and also for those which may be of rather weak density. You should use opal as the diffuser; ground glass is not sufficient. As regards the lamps, you want high power, say, 500 to 600 c.p. at least, and at the same time you want the filaments of the lamps parallel with your diffusing screen. Unfortunately, most of the half-watt lamps are made with the filament horizontal when the lamp is in the right position for burning, an arrangement which suits a vertical enlarger all right, but is a waste of light when the diffusing screen is vertical. Therefore, unless you can get half-watts with the filaments in the vertical position, your best plan is to choose from the ordinary metal-filament lamps of high power. There is nothing much in a parabolic reflector. You will do just as well with a curved or even a flat reflector of white Bristol board.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will be placed there whenever its regular position is required for notices relating to the forthcoming "B.J. Almanac."

The 1920 Almanac.

The fifty-ninth annual issue of the "British Journal Almanac" is now printing, and, barring unforeseen circumstances, will be on sale during the first day or two of February next. The time may seem long, but the "Almanac" is a big book, and, moreover, it still seems impossible to obtain productive work such as printing, and particularly binding, within a space of time as short as that in pre-war days.

The "Almanac" will be issued in its pre-war edition of 25,000 copies—apparently none too many for the great demand for it in all parts of the world. It will be issued at 1s. 6d. net, in paper covers; 2s. 6d. net, cloth bound. This early opportunity is taken of suggesting to those who desire to make certain of obtaining a copy that an order should be placed forthwith with a photographic dealer, bookseller, or railway bookstall.

One feature of the forthcoming book is a lengthy editorial article on "Beginners' Failures in Photography." The many practical hints contained in these pages are arranged upon a utility plan which makes it the easiest matter for the photographic tyro to discover the cause of a defect in negative-making and printing, and to learn the remedy or preventive. Although written primarily for the less-experienced photographic worker, it will probably be found that these notes are not without interest to those who can claim a considerable knowledge of photographic processes.

Practical progress in photography obtains its customary survey in the "Epitome of Progress," which will once again be an important section of the "Almanac." Other sections, such as those of Formulæ and Tables for everyday use, have been revised, and, wherever judged advisable, restored to the full length and scope to which users of the "Almanac" were accustomed in pre-war issues.

EX CATHEDRA.

Foggy Days.

The weather during the past few weeks has been quite seasonable, or, in Air Force parlance, "visibility is low." To photographers this means that the light is poor and that flat negatives are the order of the day. However, there are few studios now that are not provided with electric light, so that exposures are always possible, but there is so far no means of clearing the atmosphere, despite the promises of experts to precipitate the suspended carbon by electric discharges. There are fortunately some ways of mitigating the trouble caused by fog in the studio, which photographers should not overlook. One is the employment of a short-focus lens as can be used without causing noticeably bad drawing, so that as little atmosphere as possible intervenes between lens and sitter. Another is to screen off all light which is not actually falling upon the sitter. If two exposures be made, the same sized image being obtained in each case, one with a 16-in. lens and the other with a 10-in., it will be found that the latter is appreciably more brilliant, and a further improvement can be made by building a sort of tunnel with backgrounds or screens so that the camera end of the studio is in shadow. Full development should be given so as to secure as much contrast as possible, and although the negatives may look rather muddy, they will yield fairly bright prints.

* * *

Quartz Lenses.

Any practical suggestion from so experienced and judicious a photographer as Dr. D'Arcy Power, of San Francisco, commands respectful attention. Therefore, when Dr. Power reports, in the current issue of "Camera Craft," on inexpensive $f/4$ lenses, we do not dismiss his remarks as prompted by insufficient information or undue enthusiasm. Dr. Power had made for him, at the cost of 5 dollars, by the Hanovia Chemical and Manufacturing Co., of Newark, New Jersey, a $4\frac{1}{2}$ -in. $f/4$ lens of quartz or rock crystal, the performance of which in landscape or portraiture he shows in some very fine reproductions. The lens, which is of the single meniscus type, does not give critically sharp definition at full aperture, or, indeed, when moderately stopped down. It yields, on the contrary, an image of very moderate and pleasing "soft-focus," the diffusion being just about of the degree which is now widely popular in professional portraiture. But, unlike partly corrected spectacle lenses, such as have been used by M. Puyo and others, it works almost to focus, whilst, in comparison with objectives of more complex construction, its rapidity is, no doubt, greater than is commonly indicated by the f number. There seems no good reason why a lens of this kind should not serve admirably for portraiture as well as for pictorial landscape. If a single $4\frac{1}{2}$ -in. instrument can be specially

made for about £1, the cost in the regular way of manufacture should be of the order of one-quarter that of the Petzval or an anastigmat type.

* * *

Real Window Dressing. A Manchester photographer, so we read, in a newspaper report reprinted on another page, has surely achieved a record in providing an attractive display in his window. He there showed a live pony and donkey, which are used as accessories in the studio by sitters desirous of being photographed as highwaymen or Wild West cowboys. It is not intimated to us in which of these characters the sitter is mounted on the donkey; but, however that may be, the success of the idea can have no better testimony than the fact that the crowd around the photographer's window obstructed the ordinary traffic of the street, so that the police ordered the proprietor to withdraw the animals from public view. Apart from the novelty of the style of portraits, the photographer seems to have realised the truth of a favourite dictum of the late Augustus Harris's when manager of Drury Lane Theatre, to the effect that the public will always come in its crowds to see inside a building what they can see for nothing outside. The incident arouses another thought. If it is true that what Manchester thinks to-day, England thinks to-morrow, we must apparently prepare ourselves for surprising displays in photographers' shop-windows.

* * *

Artificial Lighting. Those photographers who are unable to obtain electric current have practically no choice except between incandescent gas and the magnesium flash. Both these have their own particular disadvantages, the former that of excessive heat, and the latter the difficulty of keeping the studio clear of smoke. In many cases, either of these defects can be removed by the simple expedient of placing the light outside the studio windows and working as if using daylight. The only modification necessary, except a box or cover to protect from the weather, would be a hinged or sliding panel to allow the light to be adjusted. The use of magnesium ribbon is, in our opinion, not sufficiently appreciated by photographers, as its steady light can be tolerated by many sitters who are disturbed by the sudden flash. Moreover, there is no danger of explosion, and the ribbon can be kept indefinitely without deterioration. If necessary, the ribbon can be burned in a comparatively small box with a glass or fabric front inside the studio, and the smoke allowed to condense between the exposures.

SUMMARY.

An Australian contributor, Mr. Anketell Henderson, sends us a description of certain very interesting improvements in optical and enlarging lanterns. These consist chiefly in provision for the use of lenses of different focal length and in means for automatically adjusting the position of the light-source appropriately to the focal length of lens which is being used. (P. 720.)

The separation of the lenses in stereoscopic photography of small objects on the same or an enlarged scale is the subject of a short contribution by Mr. Charles E. Benham, in which a working rule and formula are offered for discussion. (P. 725.)

In a leading article we appeal to photographers to take a firm stand against the making and issuing of photographs which are offensive to good taste. We urge also that firms of all descriptions in the photographic trade should discountenance the practice, which appears to be widespread among those ordering portraits, of getting unfinished proofs copied at a cheap rate as a substitute for purchasing the finished prints. (P. 719.)

We regret to have to announce the sudden death of Mr. H. V. Hopwood, a librarian in the Patent Office and well known also for his work on the history of cinematography. (P. 726.)

Vignettes. In one form or another the vignette picture is always in fashion, but unfortunately the vignetting is not always done in a skilful way, which is perhaps not to be wondered at when it is recollected that nearly all work is now done on development papers, and that there is no opportunity of correcting errors as the printing proceeds. One great help to successful results is to be found in the camera-vignettors, which allow of a vignettted image on a background of any tint, light or dark being obtained by straightforward "solid" printing. A hint which may be useful to those who find a difficulty in getting the lower part of the margin uniform in depth with the upper is to look at the image on the screen at as great a distance as the focussing cloth or canopy will allow. When vignetting with ordinary negatives in a printing box it is sometimes difficult to decide how far any given opening will spread over the image. This can easily be seen by placing a thin piece of ordinary white paper, not oiled or waxed, on the negative as if a print were being made. The illuminated portion and the degree of softening at the edges are then plainly visible and the vignetting card can be moved until the desired effect is obtained.

* * *

Names on Mounts. In the by-gone days, when gold bevel-edged mounts were universally used, it was the usual thing for the photographer to utilise them for advertising purposes to the limit of their capacity. Not only was the name and address printed or embossed upon the front, but the back was usually filled with such information, including reproductions of medals, Royal coats-of-arms, etc., as the photographer thought would be interesting to his patrons, or, perhaps more likely, beneficial to his business. Now the pendulum has swung the other way, and we have a plain piece of paper bearing on the front a pencilled signature, or even a monogram or cartouche, with some more or less cryptic sign. Except in the case of very eminent artists, there are certain disadvantages attached to this practice, as a recent experience showed. A visitor called upon us with a photograph of a deceased relative mounted in the modern way with a more or less illegible monogram beneath it. Fortunately, we were able to identify it, with the result that the photographer received an order, otherwise the portrait would have been sent to another photographer to be copied. Some years ago Mr. Essenhigh Corke suggested attaching a very small label with the artist's name and address to the back of the mount, and this, we think, is a sensible practice.

A new field in the intensification and reduction of negatives is opened up by the experiments set forth in a communication from the Eastern Research Laboratory, according to which the pyro developer may be used as either an intensifier or a reducer. (P. 721.)

In his article this week "Practicious" deals with the making of natural poses of the figure in studio portraiture, and has a number of hints to give on such matters as the arrangement of the hands and the use of the camera. (P. 724.)

At the Royal Photographic Society on Tuesday evening last Mr. H. F. Farmor gave a most successful demonstration of the improved version of Mr. Manly's Ozobrome process which he has entitled "Carbro." (P. 729.)

Mr. Clement Shorter has written to the "Times" pointing out that he was the first to produce an illustrated newspaper consisting entirely of half-tone reproduction. (P. 727.)

A colour-sensitising formula for use in a system of two-colour photography is the subject of a recent patent. (P. 728.)

An inexpensive single lens of $f/4$ aperture is favourably spoken of by Dr. D'Arcy Power. (P. 717.)

A Manchester photographer has secured prominent advertisement by displaying a live donkey and pony in his shop window. The animals are used for portraits of sitters in the rôle of "highwaymen and Wild-West cowboys." (P. 718.)

Foolish Competition. The high price of photographic materials has had one salutary effect on the prices of portraiture, inasmuch as it has justified making more remunerative charges than were in vogue in the cheaper classes of business when competition between manufacturers enabled photographers to cut prices to a dangerously low level. Before the price of materials falls to any considerable extent it would be well if photographers, outside the Cheap Jack class, could come to some agreement as to a minimum price for the cheaper grades of work, such as postcards and the so-called cabinet panels. Not very long ago many businesses were only made to pay by employing sweated juvenile labour and using the cheapest materials. In one case which came under our notice the highest paid employee in a business offered for sale was the receptionist at 10s. per week: the bulk of the work was done by apprentices (!) and ex-apprentices at salaries varying from 2s. 6d. to 8s. weekly. Such methods are scandalous, and we trust that photographers will be able to get together and make them impossible in the future.

SOME MATTERS OF ETIQUETTE.

THERE are one or two matters which have come greatly to our notice of late, and call for the serious consideration of photographers in a professional rather than in a commercial spirit. Maxims of etiquette are, we fear, not so widely observed as they should be, however much may be said by photographers in the way of claiming professional status. Yet, inasmuch as the war, by bringing heads of frankly commercial undertakings more closely together, has done much to establish a more definite code of ethics in many trades, we may reasonably look for signs of a wider appreciation of the same idea among photographers. It is in this spirit that our notes call for consideration.

The first matter is the making of photographs which, by reason of their objectionable character, are offensive to good taste. It is difficult always to draw a sharp line between what is indecent and what is not, but it can, at any rate, be said that photographs to which some photographers do not hesitate to put their names come very near to this line. We have had several examples of them shown to us within the last few weeks, and have been astounded that any man who sought to maintain the impression that he carried on a reputable or even a respectable business should allow his name to appear on them. The theatrical profession, which of late has permitted itself, and is permitted, a larger measure of licence than formerly, has, perhaps, something to do with this tendency. But a photographer must be very short-sighted indeed if he thinks that a presentation which may be permitted in a stage scene, where perhaps it lasts for only a few minutes, is without offence when it is embodied in the form of a photograph taken under altogether different conditions. Photographers as a whole should not be deterred by any fear of being dubbed Puritanical in doing everything they can to discourage the making and issuing of photographs of this character. The practice did great harm to photography as a whole a generation ago, and it will do the same again unless photographers, who may be quite certain they have public opinion with them, will leave no stone unturned by way of dissociating themselves from it. Usually, the means of doing so is readily found: where photographs or postcards of an objectionable character are offered for sale, the local authorities will almost always take action in respect to them on their notice being drawn to the matter. Photographers owe it to themselves that they should be the people to be the first to do this. We had an instance only quite recently of a very objectionable photograph being circulated under his own name by a photographer in a seaside resort. On a photo-

grapher, into whose hands one of the photographs came, bringing it to the notice of the Corporation, he received official thanks for his action in the matter. Probably cases of this kind are most frequently to be found in the more popular coastal pleasure resorts, the local authorities of which certainly have an interest in correcting the impression which such photographs give.

The other matter to which we wish to refer is the copying of unfinished proofs which are sent to a sitter. We have good reason for saying that this practice is now of much larger dimensions than perhaps any individual photographer imagines. A sitter is sent, perhaps, half-a-dozen proofs in the form of untuned P.O.P. prints or rough proofs on a development paper. Although the photographer may specifically ask for the return of all the proofs with the order, or may even make their return a condition of the transaction, there is still the opportunity between getting and returning the proofs for the sitter to have them copied. The legal right of the sitter to do so is somewhat obscure. So far as copyright is concerned, it was definitely held by a court years ago that copyright in all the photographs taken at a sitting became the property of the sitter, even though he or she ordered photographs from only one or two of the negatives. As regards the position in common law, we cannot recollect that a judgment deciding an issue of this kind one way or the other has ever been given, but it is perfectly obvious that a sitter who sends such proofs to be copied thereby supplies the photographer with the best possible evidence (if it could be ascertained) that the work is considered satisfactory, and that therefore the sitter is liable for such charges as a photographer makes for sittings only—that is to say, in respect to the making of the negatives from which no photographs are ordered. Unfortunately, it is probable that in most cases a photographer is not able to find out that his proofs have been copied. In some cases such work is offered to other photographers, the majority of whom, we are glad to think, unhesitatingly refuse it, and refer the customer to the studio at which the negatives were made. On the other hand, there are the cheap copying firms, many of whom, apparently, have no such scruples, whilst in these days many people can find some amateur photographer among their friends, and can get the copies made by him, without perhaps allowing him to realise the very shabby treatment of the photographer who took the negatives which his assistance makes possible. We draw attention to this matter because, no doubt, there are still some photographers who do not sufficiently regard this copying of proofs as a flagrant breach of etiquette. We think, also, that work of this kind should be declined without exception by firms undertaking the ordinary work of printing and enlarging. We know that it is the custom of the largest photographic firm in the country to return all such orders to the customer, whether the latter be the individual owner of the proofs or a dealer into whose hands they may have been placed. Such action is dictated by a correct idea of what is common fairness, and we hope that individuals and firms undertaking trade work will set their faces against these paltry attempts to deprive the photographer of business which is legitimately his. We are here referring only to proofs which are submitted for approval. The same arguments do not apply to finished portraits, which obviously are the customer's own to do what he likes with. Whatever may be thought of the wisdom of having cheap copies made of them, there is no ground for calling it by an ugly name. What we have said is also a reminder to photographers that they themselves should not omit measures, such as defacing proofs with a perforating stamp, which will do a good deal, though not all that is necessary, to prohibit this illegitimate copying.

IMPROVEMENTS IN OPTICAL AND ENLARGING LANTERNS.

For over forty years the writer has used, when lecturing, a projection lantern with two lenses, one about 7-in. and the other $1\frac{1}{2}$ -in. focus, and by having a slotted frame for the slide carrier near the lenses and reversing a nose-piece carrying the lenses, he has been enabled with the $1\frac{1}{2}$ -in. lens to project portions of the slide at increased magnification, often, in the case of buildings, nearly up to full size. By using the lantern slide in a special carrier and covering with velvet the inside faces of the slotted frame, the carrier and slide would remain stationary, and any portion of the slide could be examined in detail, focussing being effected by an arrangement like a focusing jacket. The writer will never forget the cries of delight from the audience when he first used this arrangement, showing the porch details of Amiens Cathedral about one-third full size on a big screen.

For many years the $1\frac{1}{2}$ -in. lens was used with this lantern for enlarging special portions of negatives, both portraits and buildings.

Fig. 1 is a sketch of this projection lantern, which is an invaluable instrument to anyone lecturing on technical subjects. As the position of the light had to be a little nearer to

Fig. 1.

the back for the illumination of the $1\frac{1}{2}$ -in. lens, a stop for each position of the light was provided in the lantern base, and the change could instantly be effected by a pull or a push. So far as the writer knows, no similar instrument has ever been described.

About eight years ago this principle was applied to an enlarging lantern, the bellows being removed and a series of slotted frames substituted to hold the negative-carrier at different distances from the condenser, and so allow shorter focus lenses to be used: with the $1\frac{1}{2}$ -in. lens before mentioned, nearly full-size heads could be obtained from large group negatives. Further, vest-pocket negatives could be placed in the slot at a bright portion of the cone of light away from the condensers, and with a 3-in. lens enlargements made in half the time.

A further improvement was made this year. The bellows of the enlarger was not removed but cut in two halves, and an extra and movable slotted frame for the negative-holder was provided. This was carried by two brass tubes fitted with racks and passing through the usual fixed slotted frame, and actuated to slide to any position by a pinion at the back of this frame. This extra frame was made of sheet brass with square holes, and stiffened by angle-edges, into which the bellows folded when contracted. In a new enlarger the extra slotted frame could be carried by an upper slide in the enlarger base, the lens board being carried by a lower slide, this being cheaper than brass rod and double racks, etc.

This improvement in the enlarger has given the writer so much pleasure that he hopes others and manufacturers will adopt it. Bits out of old negatives often give charming pictures, and faces out of groups, especially children, have given a new interest to photography.

Fig. 2 is a sketch of the new enlarging lantern, which is shown with parallel bellows. It works with tapered bellows if the taper is not too great. The thinner the material for the bellows, the greater the range of effects.

As to lenses, the writer generally uses three— $1\frac{1}{2}$ ins., 3 ins., and 6 ins. Each lens is fitted with a lens board, and it takes about half a minute to change from the 6-in. lens, giving nearly

Fig. 2.

five diameters, to the $1\frac{1}{2}$ -in., giving about sixteen diameters. The $1\frac{1}{2}$ -in. was a "Pistolgraph" lens made by Dallmeyer, aperture $f/2$, for which the writer gave its weight in gold about forty-three years ago. Dallmeyer's Cameo lens, about 2 ins., has been used by one of his friends. Good cinema lenses of 2-in. focus can often be picked up. For vest-pocket negatives the writer uses an Aldis 3-in., with excellent results. A slight alteration of the lens board would allow the V.P. camera itself to be used for projection if the lens were a doublet.

When diffusion is required in the enlargement, many use a cap on the lens, perforated and covered with chiffon, but this gives no latitude. By inserting a frame covered with chiffon in the central slotted frame and racking backwards and forwards, diffusion can be varied at will from a bare diffusion to a great one. By using a frame of white chiffon a wonderful softening of a hard negative can be produced.

The writer experimented with an enlarger with two moving intermediate slotted frames, so as to be able to use chiffon when enlarging with shorter-focus lenses, but found the two awkward to handle in a darkroom, and does not recommend more than one.

Another convenience of the new arrangement is the use of a vignetter in the intermediate slotted frame, as, by racking backwards and forwards, the vignette is enlarged or contracted at will.

The writer's vignetter consists of a wooden frame to fit the slot and open at the top. The vignetter hangs by hooks from the top bar of a wire frame sliding in grooves in the wooden frame, and the wire frame may have a rack actuated by a pinion to raise and lower it. The vignetter consists of a metal plate with a large opening in the centre. The edges of the plate are folded over to form a frame to carry the vignetting card suitably perforated to the shape required. The bottom of the plate is weighted with lead or other metal, and as it swings backwards and forwards on the top wire of the inner frame it gives the necessary softening of the vignette on the easel.

Fig. 3 gives an isometric sketch of the vignetter.

To use the vignetter, or diffuser, when the intermediate slotted frame is in use the writer uses a cantilever frame to carry the vignetter or diffuser. This consists of two brass tubes united by a bar of wood in front, the back of the tubes

passing through eyes screwed into the base of the enlarger. This cantilever is shown dotted in fig. 2, the top of the front bar being level with the bottoms of the fixed and moving slotted frames.

One of the adjustments liable to be forgotten when enlarging is the focussing of the light after the negative is focussed. It

Fig. 3.

involves the taking out of the negative holder and replacing it, and sometimes recentering of the negative.

The writer first experimented with levers of various shapes to focus the light automatically, and about ten years ago adopted a simple straight lever—even for the smallest size of incandescent burner he finds the straight lever efficient for focussing the light. A strip of brass, a few screws, and some stout brass wire are all that is required in most cases, and the following simple operations all that are necessary.

First focus the negative and then the light for an enlargement of $1\frac{1}{2}$ in. diameter, say from a quarter to half-plate, and mark the position of the light-tray and the lens carrier respectively. Second, focus the negative and then the light

for an enlargement of, say, four diameters, and mark the new positions of light-tray and lens-carrier. Both will be found to have moved an inch or more, and both in the same direction. With a 6-in. lens the movement will be about $2\frac{1}{2}$ ins., and with the usual condenser the movement of the light-tray will be something less. Let us assume $1\frac{1}{2}$ in. To ensure proper focussing of the light we must connect lens to light by a lever to move in these proportions. The author has found that a lever about three times the length of the largest of these dimensions to be a good proportion. Multiplying $2\frac{1}{2}$ and $1\frac{1}{2}$ by 3 gives $7\frac{1}{2}$ and $4\frac{1}{2}$. Take a strip of brass about $8\frac{1}{2}$ in. \times $\frac{5}{8}$ in. \times $\frac{1}{8}$ in., and drill two holes, A and B (fig. 4) $7\frac{1}{2}$ ins. apart, and with a screw through end A pivot the lever to the base of the lantern (under the condenser is preferable) and connect the other end B by a stout wire to the lens board. At $4\frac{1}{2}$ ins.

Fig. 4.

from the pivot end drill a smaller hole C and connect by wire to the light-tray. The light-tray should be made to slide easily. The wire connection may be made under the lamp box or inside the lamp box, as most convenient, and it is advisable to use in the measurings the longest focus lens you use, about 6 ins. for a $\frac{1}{4}$ -plate.

When this is completed we shall have an optical system in which the light is always in proper focus for the projecting lens in any position it may be required, and any shorter focus lens may be substituted for the usual projecting lens, if provision be made for the negative carrier at a suitable distance for the lens, as can be done with the improved enlarging lantern just described.

ANKETELL HENDERSON.

INTENSIFICATION AND REDUCTION WITH PYRO DEVELOPERS.

A Communication from the Research Laboratory of the Eastman Kodak Company.

IN the course of a study of the colour of photographic negatives developed in pyrogallol developers, it was suggested by Mr. L. A. Jones, of this laboratory, that the alteration of this colour might be utilised as a method of photographic reduction or intensification. It is a matter of common experience among photographers that a pyro-developed negative has a greater printing density and contrast than a neutral negative of equal visual density and contrast. The strength of the pyro colour can be varied over a wide range by suitably altering the concentrations of constituents of the developers, especially that of the sulphite. A pyro developer without sulphite gives an extremely yellow negative, while sufficient sulphite can be added to the developer to produce a negative with no visible yellow colour.

Several methods of photographic intensification involve bleaching the negative and subsequent re-development in a solution which gives it a greater photographic contrast. By re-developing in a pyro formula the amount of intensification or reduction can, within certain limits, be controlled at will by varying the sulphite concentration of the developer. Where the greatest reduction is desired, re-development in some such

developer as Elon gives lower photographic contrast than any pyro formula.

For bleaching the negative, there are two possibilities: a ferricyanide bleach leaves pyro stain in the negative, while a permanganate bleach removes the stain. Thus, the pyro colour may be left in the negative, and more colour added by re-developing in pyro; or the colour can be removed and a different amount of colour substituted by re-developing in the proper formula.

The present experiments were made to determine the possibilities of this method, and to measure the amounts of intensification or reduction obtained under various conditions. Any intensification or reduction by this method consists in altering the colour of the photographic deposit; little change is produced in the visual density values of the negative; therefore, the amount of intensification or reduction must be determined by printing upon some positive material. The printing medium used in those experiments was positive motion-picture film. The negatives to be intensified or reduced were all made on Seed 30 plates.

The procedure was as follows: A 10 x 8 plate was exposed

in the sensitometer to 22 steps, in which the exposures increased by successive powers of $\sqrt{2}$. The areas having equal density were about $\frac{3}{8}$ in. wide and extended across the short dimension of the plate. This plate was developed, fixed in plain hypo, washed, and dried. It was then cut into eight strips, each 1 x 10 ins.; each of these strips contained the same series of densities. Three of these strips received no further treatment. The other five strips were bleached in the same way, and each re-developed in a different formula. When dry, all eight of the strips were mounted together upon a 10 x 8 sheet of clear glass. All the strips were then printed at one time upon a 10 x 8 sheet of positive film, care being taken to print from the "straight line" portion of the strips upon the "straight line" portion of the film.

The "straight line" portion refers to those densities which give the straight line portion of the H. and D. curve of the material. The printing light came from the flashed opal glass window of a white-lined box, illuminated by a gas-filled tungsten lamp. The print was developed in Elon-hydroquinone developer to a gamma of about unity. The resulting densities were read, and the density values were plotted against the logarithm of the exposures given the original negative.

These curves were the reproduction curves, and show in each case how the final positive rendered the original exposures. The greater portion of each of these curves was a straight line. The ratio of the slope of this line for an intensified or reduced negative to the slope for an untreated negative expresses the degree of intensification or reduction; it is the ratio of the effective photographic contrast of the treated negative to that of the untreated negative. This ratio will be designated as

$\frac{\gamma_{ip}}{\gamma_{op}}$, following the terminology of Nietz and Huse¹. The "effective photographic contrast" means the photographic contrast obtained under the practical conditions of these experiments, and does not mean necessarily true photographic contrast; methods for the determination of true photographic density and contrast are given in "The Spectral Selectivity of Photographic Deposits," by Mr. L. A. Jones and the present writer².

Where the value $\frac{\gamma_{ip}}{\gamma_{op}}$ is greater than unity, the effect has been an increase of photographic contrast or intensification; and where $\frac{\gamma_{ip}}{\gamma_{op}}$ is less than unity, it represents a decrease of photographic contrast, or reduction of the negative.

By the above procedure each strip of a plate was carried through identically the same process, except for the bleaching out and re-development in various developer formulæ. Any changes in printing contrast observed were due to the bleaching and re-development process. All the negative strips of a set were made upon one plate, which was developed as a unit; the final strips of each plate were printed upon one sheet of film, which was developed as a unit. By this method, any errors due to variations in development or in photographic materials were minimised.

The original negatives were developed in one or the other of these two formulæ:—

Pyro (5-10-10).

Pyro	5 gms.
Sodium carbonate (dry)	10 gms.
Sodium sulphite (dry)	10 gms.
Water to	1,000 c.c.s.

Elon-Hydroquinone (EH ₈₀)	4 gms.
Hydroquinone	1 gm.
Sodium carbonate (dry)	25 gms.
Sodium sulphite (dry)	75 gms.
Potassium bromide	1.5 gms.
Water to	1,000 c.c.s.

The negatives were developed to visual gammas between 0.5 and 1.0. There was no indication that the value of the gamma of the original negative had any effect upon the value of $\frac{\gamma_{ip}}{\gamma_{op}}$.

The bleaching solutions were made up as follows:—

Ferricyanide Bleach.

Potassium bromide	10 gms.
Potassium ferricyanide	30 gms.
Water to	1,000 c.c.s.

Permanganate Bleach.

A.—Potassium permanganate	4.5 gms.
Water to	1,000 c.c.s.
B.—Sodium chloride	160 gms.
Sulphuric acid	40 c.c.s.
Water to	1,000 c.c.s.

For use, take A, 1 part, B, 1 part, water 6 parts.

After bleaching in permanganate, the negative is cleared in $\frac{1}{2}$ per cent. solution of sodium bisulphite.

After bleaching the five strips of each set in ferricyanide or permanganate, they were exposed to a strong light and re-developed, one strip in each of these developers:—EH₈₀, pyro (5-10-0), pyro (5-10-5), pyro (5-10-10), and pyro (5-10-25); the figures in parenthesis represent successively the concentrations of pyro, sodium carbonate, and sodium sulphite in grams per litre of developer³. The re-development was carried to completion, about five minutes' usually being sufficient for this.

Table I. gives the values of $\frac{\gamma_{ip}}{\gamma_{op}}$ obtained with the various solutions used; each value is the final average obtained from three or four negatives; from one to three prints had been made from each negative.

TABLE I.

	Original development EH ₈₀ Permanganate bleach.	Original development EH ₈₀ Ferricyanide bleach.	Original development Pyro 5-10-10 Permanganate bleach.	Original development Pyro 5-10-10 Ferricyanide bleach.
Re-development	$\frac{\gamma_{ip}}{\gamma_{op}}$	$\frac{\gamma_{ip}}{\gamma_{op}}$	$\frac{\gamma_{ip}}{\gamma_{op}}$	$\frac{\gamma_{ip}}{\gamma_{op}}$
Pyro 5-10-0	2.00	1.70	1.15	1.80
Pyro 5-10-5	1.50	1.35	.95	1.40
Pyro 5-10-10	1.15	1.15	.80	1.15
Pyro 5-10-25	.95	1.00	.65	.95
EH ₈₀	.80	.95	.55	.85

These data are shown graphically in the curves of Figs. 1 and 2, where $\frac{\gamma_{ip}}{\gamma_{op}}$ is plotted against the sulphite concentration of the pyro re-developer.

Table II. shows the effect of repeating the process, bleaching each time in ferricyanide and re-developing in pyro (5-10-0), to increase the amount of colour in the negative.

TABLE II.

	Original development EH ₈₀ Ferricyanide bleach.	Original development Pyro 5-10-10 Ferricyanide bleach.
Re-development	$\frac{\gamma_{ip}}{\gamma_{op}}$	$\frac{\gamma_{ip}}{\gamma_{op}}$
Pyro 5-10-0	$\frac{\gamma_{op}}{\gamma_{op}}$	$\frac{\gamma_{op}}{\gamma_{op}}$
Once	1.70	1.80
Twice	2.10	2.20
Three times	2.40	2.45
Four times	2.65	2.70
Five times	2.80	2.85

¹ "The Sensitometry of Photographic Intensification," A. H. Nietz and K. Huse, Jour. Frank. Inst., March, 1918, pp. 389-408.

² "Jour. Frank. Inst.," February, 1918, pp. 231-267.

³ C. E. K. Mees, A New Method of Writing Developer Formulæ, "B.J.," Vol. 64, 1917, p. 535.

Thus the process is capable of successful repetition, in case the previous treatment has been found insufficient. When the process is repeated several times, care must be taken to avoid injuring the softened gelatine surface.

The data of Table I. show that the process is suitable for the intensification of either pyro or Elon-hydroquinone negatives, and for the reduction of pyro-developed negatives. A slight reduction in an Elon-hydroquinone negative is pro-

Fig. 1.—Original Development, Pyro 5-10-10. Curve 1, Ferrioyanide Bleach. Curve 2, Permanganate Bleach. Re-development Pyro 5-10-x.

duced by bleaching in permanganate bleach and re-developing in Elon-hydroquinone. By re-developing in pyro, any intensification up to double the original photographic contrast can be secured. Nearly as much intensification can be obtained upon pyro (5-10-10) negatives by bleaching in ferrioyanide and re-developing in pyro. A pyro (5-10-10) negative can be reduced to almost half its original photographic contrast by bleaching in permanganate solution and re-developing in Elon-hydroquinone. Of course, the amount of reduction possible in this way depends upon the amount of colour in the original negative. Pyro (5-10-10) gives about the same colour as many recommended pyro formulæ.

This method, of course, may be applied with other developing formulæ than those given here. These experiments serve

to show the practicability of using the pyro colour as a means of photographic intensification, or the removal of it as a means of reduction.

The advantages of this method are that within certain limits any degree of intensification or reduction can be produced by suitable variations in the sulphite concentration of the pyro re-developer; furthermore, the amount of intensification or reduction is predetermined; it does not depend upon the time

Fig. 2.—Original Development E100. Curve 1, Permanganate Bleach. Curve 2, Ferrioyanide Bleach. Re-development Pyro 5-10-x.

for which the negative is bleached or re-developed, since these processes are carried to completion. The degree of intensification or reduction that can be obtained by this method compares favourably with that of other methods. Nietz and Huse determined $\frac{\gamma_{IP}}{\gamma_{OP}}$ for ten intensifiers; only four of these gave a value exceeding 2, and five of them gave less than 1.5. The fact that the reproduction curves obtained in these experiments have long straight line portions shows that, over the range of densities used, the reduction or intensification is proportional—that is, the contrast is changed by the same ratio for all parts of the negative.

R. B. WILSEY.

FORTHCOMING EXHIBITIONS.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Sec.: John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow.

KEROTYPE DEMONSTRATIONS.—By arrangement with Messrs. Marion and Co. the Kerotype process is being demonstrated this week in Messrs. Marion's showrooms, 3, Soho Square, W.1, from 12 noon to 6 p.m., and at the same time a very interesting collection of results by the process is being shown. The great facility of Kerotype paper, as many of our readers doubtless know, consists, first, in its development, fixing and toning like any other development paper, and, secondly, the transfer of the picture to any flat or shaped surface. The process thus lends itself to the production of an immense variety of distinctive effects, some of the most charming of which are those in which the image is transferred to a fabric and the latter dry-mounted in the ordinary way. Professionals will be particularly interested in these latter results, but it is intended to arrange shortly a further exhibition in which the use of the process for professional purposes will be the chief consideration. In the meantime any amateur worker will gather many interesting suggestions from the specimens which are shown. Full technical particulars as to the working of the process may be obtained on application to Kerotype, Ltd., 106a, Upper Tooting Road, London, S.W.7.

THE BIRMINGHAM PHOTOGRAPHIC SOCIETY, after its many moves during the past five years, has secured new rooms at the Birmingham Medical Institute Buildings, Edmund Street (next to the School of Art), and a house warming takes place on December 16 in the form of an autumn and excursion exhibition, which on this occasion is "for members only." As soon as the Society is once again in its stride we hope to see a revival of the annual exhibition, for which it justly had an international reputation. Up-to-date enlarging and dark-rooms are being installed at the new headquarters, and these, in addition to the attractive lecture programme, should draw many new members.

A MILD SENSATION was created recently in a Manchester street, says the "Manchester Evening News," by the appearance in a photographer's shop window of a real live pony and donkey. So large a crowd was attracted by the unwonted spectacle that the traffic was in danger of becoming impeded, with the result that the police intervened and requested the enterprising proprietor to withdraw the animals from public view. A printed notice is now prominently exhibited in the window to the effect that owing to police regulations the pony and donkey have been relegated to the rear of the shop, where customers desirous of being photographed as highwaymen or Wild-West cowboys can be camouflaged as such astride one of these animals.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).

Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).
 Reduction of Negatives and Prints (Aug. 29).
 Leaky Roofs (Sept. 5).
 Blinds and Curtains (Sept. 12).
 Miniatures (Sept. 19).
 Printing Portrait Negatives (Sept. 26).
 Wedding Groups (Oct. 3).
 Combination Printing (Oct. 10).
 Flashlight Work (Oct. 17).
 Flashlight Portraiture (Oct. 24).
 The Question of Outfit (Oct. 31).
 Telephoto Lenses for Professional Work (Nov. 7).
 Changing Quarters (Nov. 14).
 Carbon Printing—I. (Nov. 21).
 Carbon Printing—II. (Nov. 28).
 Bromide Wrinkles (Dec. 5).

NATURAL POSES OF THE FIGURE.

Posing the human figure so as to give results which are satisfactory to the cultivated eye is not an easy matter—in fact, some photographers who lack the necessary quickness of perception never acquire the art at all, but content themselves with half-a-dozen stock positions and rest content with them. Others, however, feel the necessity for natural and pleasing arrangements, and often feel discouraged through their inability to induce graceful poses with unpromising subjects. To such I would try to give comfort, by pointing out the laborious work often lasting for years which the painter has to endure before he acquires proficiency in figure drawing. The photographer is distinctly better off, for he has not to go through the pangs of learning to draw, but can concentrate his attention on learning what constitutes a graceful pose, and, what is equally important, recognising one when he sees it.

There is no better way of acquiring a knowledge of posing than by studying paintings and drawings by good artists, not with the idea of copying the pictures closely, but rather of absorbing their spirit and acquiring what many people imagine to be "the artistic instinct," but which is really the result of cultivating such natural taste as the student originally had in his nature.

It must be conceded that the style and individuality of the model are important factors in the production of a picture. For example, it is useless to try to realise a conception which depends on a tall and graceful figure if the model is short and plump; here another pose which will not emphasise the undesirable characteristics must be chosen.

Nothing is so dangerous as to give positive rules for obtaining artistic poses, but generally it is desirable to avoid either full front or profile views of the figure as these lack animation and produce the undesired impression that the sitter is standing for the express purpose of being photographed. Another thing to be avoided is any attempt to manipulate the sitter into a graceful pose. This is rarely successful, the sitter either appearing stiff and constrained in the attempt to keep a position which is not natural to her, or assuming an expression of

boredom and fatigue which will nullify the effect of the most perfect pose. I well remember one very skilful photographer who treated his sitters as if they were clay models. The hands and arms were carefully placed, and every fold in the drapery carefully disposed, but by the time the exposure was made the sitter was on the verge of collapse, and looked it. Far better than this is to observe closely every movement of the sitter while in the studio before any attempt at posing is made, and to choose any position which she may take which gives promise of a picture. It is often necessary to ask the sitter to walk round the studio if the position first taken up appears at all awkward, or even to try a totally different pose, reverting to the first one afterwards. I have found it useful to tell the sitter what to do in the same way as stage directions are given. Thus I would say, "I want you to walk up to the table, pick up the photograph and turn round and tell me what you think of it." Nine times out of ten the sitter catches the idea, and the result is natural and usually more or less graceful. As I have already hinted there are certain types of figure with which a standing pose is impossible, and for these a suitable sitting position must be found which should not be a difficult matter.

With sitting figures the hands play an important part in the composition, and we are here face to face with one of our greatest difficulties. If we compare the hands of the average person with the hands as rendered by portrait painters we are driven to the conclusion that either the painters are very fortunate in finding models with small and graceful hands or that they deliberately represent them on a smaller scale than the rest of the figure. The latter course is impossible to the photographer, and he must therefore endeavour to place the hands in such a position that they appear easy and graceful and must avoid exaggerating their size by faulty management of his apparatus. Here again I urge the operator not to attempt to twist the hand or to alter the position of individual fingers, but to suggest to the sitter what is required until a satisfactory result is obtained. As a rule the hands should not be shown in their full breadth, but more or less edgewise,

and care should be taken that some of the fingers are not closed upon the palm as this frequently gives the effect that they have been amputated. Unless the hands are actually engaged in some action, such as holding a book, arranging flowers, or playing with a necklace, the muscles should be relaxed. The arm of a chair should not be gripped or the hand clenched; above all the fingers should never be interlocked as this gives an excessively clumsy appearance. Many effective poses may be obtained by resting the face upon the hands, the simplest being when the half-closed hand supports one side of the head. In this case one must be careful that the hand only touches the cheek lightly and does not push the flesh up into a lump above it. Other somewhat similar poses are obtained by placing the two open hands together and resting the side-face upon the back of one or by interlacing the finger-tips and resting the chin upon them, the elbows being of course supported upon a table.

It is when the hands rest in the lap or upon the knees that they are usually most obtrusive, and this appearance should not be aggravated by allowing a strong light to fall upon them. A small screen, placed so as to reduce the light on the lower part of the figure, will help considerably in reducing the prominence of the hands. The camera vignetter may even be employed so as to throw the lower part of the figure into semi-shadow. This dodge is extensively used by some successful workers.

The swing-back of the camera is a trap for the unwary when dealing with the hands of a sitting figure. It will, it is true, bring them into focus without reducing the aperture of the lens, but at the expense of increasing their apparent size. With the rapid plates now available it is possible to stop down to a reasonable extent and yet not to cause an unduly long exposure. I have found that excellent results can be obtained by having the camera rather higher than usual and pointing the lens downwards, thus bringing the face and hands nearly upon the same plane. When doing this it is necessary to see that the head is not depressed too much or the picture will not be satisfactory. Fortunately full length portraits are in little demand at the present time except for people in uniform or fancy dress, for in the majority of cases a three-quarter length makes a much better picture. It also places a valuable power in the hands of the photographer as it allows him to reduce the dumpy appearance of a short figure. We may take a three-quarter length of a figure which only just misses the edge of the skirt and give the appearance of a person of average height. With men, a little more care is necessary as the distance between the bottom of the coat or jacket and the edge of the picture must be nicely balanced or the desired effect will not be produced.

I must not forget to remind my readers that the power of suggesting poses to the sitter is of great value and should be cultivated, when the physical attributes of the operator permit—that is to say, that if a movement of the limbs or a pose of the hands is suggested, it is apparently unconsciously enacted by himself. If the head is to be raised or turned, or the hands moved the request may be accompanied by the appropriate gesture, generally with satisfactory results. Even farther than this it is sometimes useful to show the actual pose in the position the sitter is to occupy, and to invite him or her to copy it. Naturally this requires a little study on the part of the operator who must have a proper idea of what he looks like when he assumes certain poses, otherwise he may only succeed in making himself appear ridiculous.

PRACTICUS.

LICENCES FOR RETAIL BUSINESSES.—It has been stated in the House of Commons by Sir Robert Horne, Minister of Labour, that the operation of the Order requiring a licence before a new retail business can be started will be brought to an end on December 31 next.

LENS-SEPARATION IN STEREOSCOPIC PHOTOGRAPHY OF SMALL OBJECTS ON THE SAME OR AN ENLARGED SCALE.

A CORRESPONDENT specially engaged in stereoscopic photography of natural-history specimens often on an enlarged scale recently wrote to us as follows:—

I was much interested in the series of articles you published recently on Stereoscopic Photography.

There was one point which was not touched upon, and on which I have not been able to discover any definite information in any of the literature to which I have been able to refer.

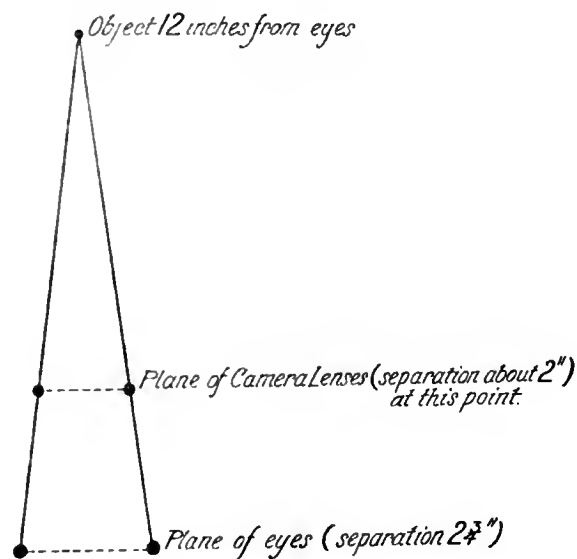

When a near object is to be photographed the separation of the lenses has to be less than the usual 3 ins. employed for distant objects.

Further, when a small object is to be photographed, say, natural size, it is impossible as a rule to get the lenses sufficiently close together, and successive exposures are made by moving a single lens a certain distance on each side of the central line. If the resulting separation is too great, excessive relief is obtained. If too little, there is insufficient relief in the finished stereograph.

The question is what is the rule connecting focal length of lens, magnification and separation to secure true stereoscopic relief?

Accordingly we referred the question to the writer of the articles, Mr. Charles E. Benham, by whom the following graphical solution of the problem is offered in the hope that others interested in the optics of stereoscopic photography may be disposed to discuss it. Mr. Benham writes:—

In the stereoscopy of small objects at a closer view point than the distance of distinct vision (which we will place at 12 ins.), the separation point of the lenses must bear the same relation to the distance from the object to the plane of the lens focal centres that $2\frac{3}{4}$ bears to 12. The following diagram will make this clear, and may be used as a scale to show separation point for the lenses at any given proximity to the object:—

The formula corresponding with this graphic construction is therefore simply $12 : 2\frac{3}{4} :: \text{distance of camera} : \text{separation distance}$. In other words,

$$\begin{aligned} \text{separation distance} &= \frac{\text{distance of lenses} \times 2\frac{3}{4}}{12} \\ &= \frac{11}{48} \text{ distance of lenses,} \\ &\text{or (approximately) } \frac{\text{distance of lenses}}{4} \end{aligned}$$

Practically, therefore, a quarter of the distance of lens from object will give the separation distance for objects at close range.

The principle applies equally to magnified objects, the separation distance being arrived at in just the same way when the position of the camera is determined on. The magnification does not vitiate

the principle, because only a smaller portion of the object comes into the field.

Acting on this formula for distances *beyond* the 12 ins. for distinct vision point, the formula would soon lead us astray, and in fact it did lead astray some who in the early days of stereoscopic practice laid it down as a principle of universal application. For objects at a distance of some yards we should introduce a separation distance for the lenses which would be preposterous. The reason for this apparent anomaly is that while 12 ins. may be regarded as the "near point," it is not at the same time the "far point" of vision, that is to say, it is not the limit of distinct vision in both directions of nearness and its opposite. The range of stereo vision with the eye is a wide one, and the separation of 2½ ins. holds good for a wide range. It is only when we want to give an effect of relief of very distant objects in the form of models seen at closer range that we can legitimately increase the separation of the lenses. On the other hand, in the photography of objects within the limit of distinct vision the proportionate approximation of the lenses holds good.

CHARLES E. BENHAM.

BRITISH PHOTOGRAPHIC MANUFACTURERS' ASSOCIATION, LTD.

ANNUAL GENERAL MEETING.

On Thursday, November 20, the annual general meeting of the British Photographic Manufacturers' Association was held at the Connaught Rooms, London, Mr. E. W. Houghton presiding. The meeting was preceded by a luncheon, at which about forty seats were occupied.

The President (Mr. E. W. Houghton), in moving the adoption of the annual report and accounts, called attention to the fact that the Association was formed during the early part of the war, and that so far its work had been mainly connected with the war. The printed report dealt with the principal business that had been carried out during the past year, and, without going into detail, he might mention that it had been of considerable assistance to the industry over a difficult period to have one organisation through which to negotiate with the various Government Departments. This was a real advantage, which had been utilised and appreciated by both sides.

Now that the war was over, he (the President) felt that the work which should be accomplished by the Association was just as important in every direction as it had been in the past. He hoped and believed that the photographic industry would never go back to the conditions which prevailed in pre-war times. Then it was customary to regard that which was everybody's business as nobody's business; manufacturers were inclined to look upon competing firms as rivals and enemies. As British manufacturers they were now banded together for the furtherance of the photographic industry throughout the world.

The question of standardisation of sizes of small-plate cameras had been decided and duly announced throughout the photographic Press of the world. The alarm expressed by some had subsided now that the objects of the Association in this matter were clearly understood.

A chart setting out the standard sizes and the numbers by which they would be known would shortly be issued by the Association to all the principal dealers and manufacturers. It would then rest with the camera-makers to adopt the new sizes for their new models. There would be no difficulty with regard to plates and papers; the manufacturers would supply to meet the demand as they always had done.

Mr. Houghton said that the second edition of "The Photographic Industry of Great Britain" was now in the press, and would shortly be distributed entirely overseas. This was in accordance with the original plan of the book. Other co-operative plans were in hand which would apply more particularly to the home country.

The President concluded his remarks by congratulating members upon the satisfactory financial position of the Association as revealed by the audited accounts and balance-sheet, and urged the advisability of a change of officers and members of Council.

A useful discussion ensued, in which a number of members participated. Keen interest in the work of the Association was displayed, and a general desire expressed that the co-operative efforts in the

interests of British photographic manufacturers should be extended on the lines suggested by the Council.

The following officers and members of Council were declared elected as a result of the ballot:—

President.—E. W. Houghton.

Vice-Presidents.—J. Hill, G. M. Bishop.

Hon. Treasurer.—E. B. Cook.

Hon. Secretary.—F. E. Greenwood.

Members of Council.—Austin Edwards, W. F. Butcher, O. S. Downing, J. R. Griffin, W. S. Hobson, T. Illingworth, F. J. Jenks, Gray Pickard, C. F. S. Rothwell, S. Whitfield.

Secretary.—Arthur C. Brookes, Sicilian House, Southampton Row, W.C.1.

DEATH OF MR. H. V. HOPWOOD.

It is with very great regret that we see the announcement of the death on Friday last, December 5, at the age of fifty-three, of Mr. Henry Vaux Hopwood, assistant librarian in the Patent Office Library, where he had followed his profession of technical librarianship for over thirty years. Personally, if not always by name, Mr. Hopwood was well known to visitors to the library at Southampton Buildings, and many have had occasion to appreciate his wide knowledge and invariable kindness and courtesy in assisting the legitimate user of the unique collection of technical books in his charge. Mr. Hopwood was the author of the handbook "Living Pictures," a semi-historical manual on the technics of cinematography, first published in 1899, and now re-issued as "Hopwood's Living Pictures," after having been largely re-written and revised by Mr. R. B. Foster. For some months before his death Mr. Hopwood, who took a keen interest in photographic literature, as well as in the practical processes of photography, had been compiling a bibliography of literature relating to the work of Hurter and Driffield for inclusion in the memorial volume to be published in due course by the Royal Photographic Society. He had in fact been engaged on this work within a few days of his death, which took place suddenly as the result of influenza, followed by pneumonia.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Glance at Developers.

A STUDY of the Answers to Correspondents page of this journal, or a conversation with a group of photographers, will lead one to the conclusion that although the average photographer knows that he may expect different results from different developers he has not usually a very clear idea as to what results he will get with any particular reagent. The following tables will, I hope, make clear the chief points of interest to the practical worker.

Two tables are necessary because the most important features for plate development may be quite a secondary consideration for prints. To give an instance, pyro metol is frequently used for plates because it makes the best of under-exposures. This is a valuable property, but when it comes to the making of prints it is no advantage whatever.

To take the plate table first. It must be quite clearly understood that the properties of any developer only hold good while it is used in a normal manner. Metol, for instance, is noted for its soft working, and yet by a plentiful use of a restrainer and long immersion in the developer it is possible to get a hard negative with it. The same applies to colour of image; the amount of sulphite, the use of potass. brom., and other things affect this greatly, so that the indications given in the tables are for normal formulæ used in a normal way. In the case of fog I have acted on different lines, as no normal developer will fog a plate of ordinary speed, unless development is carried on for a long time. I have therefore tried to give an indication of the tendency of the developer to fog the plate when development is forced.

The speed is the speed with which normal density is reached—a very different thing, it should be remarked, from the time it takes the image to come up on the surface of the plate. The keeping qualities referred to are those of the developer as usually made up for

use; pyro-soda, for example, being in its two solutions, while M.Q. would be in one concentrated solution.

Now for the paper-developer table. I have left out keeping qualities, as developer for prints is always best mixed just before use. In place of this I have put in the colour to be obtained by toning the image, the bleaching and sulphide process being used. The fog column is also left out, as no standard developer gives it. In conclusion, I should like to say that the results given here are those obtained in practical work. I do not know if they will be found to be the same with all brands of plates and papers, but I believe they will be, except in most exceptional circumstances.—ARTHUR G. WILLIS.

TABLE I.—DEVELOPERS FOR PLATES.

Reagent.	Speed	Ten- dency to Fog.	Colour of Image	Con- trast.	Keep- ing Pro- perties.	Remarks.
Amidol	Slow	Very slight	Blue Grey	Soft	Bad	A useful developer where soft negatives are wanted.
Asol ...	Medium	None	Grey	Soft to medium	Good	Very good for negatives for enlarging. Very clean.
Elkonogen..	Medium	None	Grey to Black	Soft to medium	Good	Useful for all round work.
Ferrous Oxalate	Slow	None	Black	Medium to hard	Good	A splendid developer for clean negatives, but not suitable for quantity production.
Glycine ...	Very slow	None	Black	Hard	Good	The best for slow tank work. Most exceptionally clean in working.
Hydroquinone	Fast	None	Blue Black	Hard	Good	Useful for B. and W. copy negatives, unsuitable for general work.
Metol.....	Moderate	Slight	Grey	Very soft	Good	Soft working. Better used with hydroquinone.
M.Q.	Fast	None	Black	Medium	Good	Very useful, but negatives are apt to be disappointing, rather "pretty" than good printers.
Paramidophenol	Medium	None	Grey	Soft	Good	Useful for general work.
Pyro soda..	Fast to Medium	None	Warm Black	Medium	Moderate	Best of all for all round work. Quick, clean, and negatives of good printing value.
Pyro Metol	Fast	Slight	Green Black	Medium	Bad	Makes the best of short exposures. Useful for that, but too apt to fog for general work.
Pyro Ammonia	Fast	Considerable	Brown	Medium	Bad	Most adaptable of all developers, but rather troublesome to make up.
Pyro Castic Soda.	Fast	Slight	Grey Black	Soft	Moderate	Cheapest of all. Quite good for general work.

TABLE II.—DEVELOPERS FOR BROWN AND GAS-LIGHT PAPERS.

Reagent.	Speed.	Colour of Image.	Contrast.	Colour when Toned.	Remarks.
Amidol	Moderate	Grey Black	Medium	Very good	First-class for all work, especially when much toning is done. Must be used freshly made.
Asol.....	Fast	Black	Medium to strong	Good	Very useful developer for general work, especially where most prints are left untoned.
Elkonogen....	Fast	Black	Medium to flat	Moderate	Useful for soft B. and W. prints, especially enlargements.
Ferrous Oxalate	Slow	Black	Strong	Bad	Not suitable for quantity production, but useful for a clean working developer for special work.
Hydroquinone.	Moderate	Blue Black Grey	Very strong	Bad	Not good alone; much better used with metol.
Metol (Monomet, Scalol, etc.)	Moderate	Grey	Flat	Very good	Somewhat flat-working when used alone, but prints of a good colour, and very fine for toning.
M.Q.....	Fast	Black	Medium	Moderate	This varies with proportions of M. and Q., but it is a most useful developer for B. and W. results. Not so good for toning.
Paramidophenol	Moderate	Grey Black	Medium	Moderate	Useful for all round work.
Pyro Soda	Moderate	Warm Black	Medium to hard	Moderate to bad	Very useful for warm black results without toning, but liable to stain the paper case.

Photo-Mechanical Notes.

Half-tones in Newspaper Illustrations.

Mr. Clement Shorter writes to the "Times" of Saturday last, December 6, as follows:—

"In your note on the purchase of the 'Illustrated London News' and the 'Sketch' by Sir John Ellerman you are guilty of an error in art history which is, perhaps, worth correcting, and which, not without some measure of egotism, I correct in my own interest. When I entered the office of the 'Illustrated London News' as editor exactly thirty years ago this month nearly all the blocks used in the production of that journal were woodcuts. Half-tone process was used very rarely, it being more in evidence in the 'Lady's Pictorial' than in any other journal of that date. I found that the use of half-tone process for drawings in particular was very little in favour, Mr. Bernard Partridge of all living artists being the keenest at that time for its use for his pictures. On January 3, 1891, there were 35 wood engravings in the 'Illustrated London News' to four half-tone or process blocks; on January 2, 1892, there were 21 wood engravings to 12 half-tones. By December 31 of that year there were 32 wood engravings and 28 half-tones. In founding and becoming the first editor of the 'Sketch' in 1893 I was the first to produce an illustrated newspaper consisting entirely of half-tone reproduction. The matter is, perhaps, a small one, but it is the privilege of advancing years to be guilty of reminiscence."

Commercial Aerial Photography.

The "Scotsman," in its issue of December 2 last, gives some particulars of the firm of Aerial Photos, Ltd., 81, George Street, Edinburgh. It states that, as the name suggests, the main business of the company is photography, in which they have been specialising and meeting with every success. Aerial Photos, Ltd., have been recently doing a great deal of this work for several of the large commercial undertakings in Scotland, and at present are engaged in filming the workshops of Messrs. Singers, Clydebank, while in the near future a start will be made with Weir's yards. Though this work is covered by most of the flying members of the company, many of the special commissions are undertaken by Captain A. E. Cooper, whose wonderful gifts in that direction singled him out for the post of official artist to the R.A.F. during the war. All Captain Cooper's work is done in the air, and he does not depend on the camera, but actually sketches and colours his objective while flying. At present some of his work is on exhibition in the Science and Industries Exhibition in Glasgow at the stall of Messrs. William Beardmore and Co., Ltd., the builders of the famous airship R.34. An exhibition of aerial photography is being arranged for the beginning of the year by the Glasgow Corporation, and at it the company expect to show many of the results of their ever-increasing activities.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- Applications, November 24 to 29.
- LENSES.—No. 29,442 and 29,443. Objectives for photographic, etc., purposes. L. B. Booth.
- CAMERAS.—No. 29,726 Photographic cameras. R. C. Barron and I. Castle.
- CAMERAS.—No. 29,189. Photographic cameras. H. Jowett.
- AERIAL PHOTOGRAPHY.—No. 29,232. Cameras and negatives for aerial photography. T. E. Moorhouse.
- CAMERA SUPPORTS.—No. 29,717. Supports for photographic cameras. J. M. Shaw and R. E. Strange.
- CAMERAS.—No. 9,509. Photographic cameras. G. J. Terwiel.
- CINEMATOGRAPHY.—No. 29,559. Cinematographs. R. Anderton.
- CINEMATOGRAPHY.—No. 29,703. Cinematograph shutter. E. J. Day and C. R. Deering.
- CINEMATOGRAPHY.—No. 29,724. Cinematography. S. M. Prokudine Gorsky.
- CINEMATOGRAPHY.—No. 29,320. Cinematograph films. F. L. Hancock.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR SENSITISERS FOR TWO-COLOUR PHOTOGRAPHY.—No. 134,256 (of September 25, 1918). The invention is for improvements in or relating to colour photography of the class wherein two sensitised surfaces superimposed are simultaneously exposed, and has for its object to render such colour photography more simple in operation. According to the invention, a sensitiser for the class of colour photography referred to above comprises pinacyanol, pinaverdol, pinachrome, flavasine, and ammonia, mixed with water.

Preferably the proportions employed are as follows:—

Pinacyanol	2 grs.
Pinaverdol	6 „
Pinachrome	2 „
Flavasine	4 „
Ammonia .880	4 ozs.
Distilled water	1,300 ozs.

In making up the sensitiser, the first four ingredients in the quantities stated are preferably dissolved in 10 ozs. of boiling alcohol and stirred for ten minutes until thoroughly dissolved, after which 1,300 ozs. of distilled water may be added at a temperature of about 70 deg. F., and then the 4 ozs. of ammonia. The film or plate to be sensitised is immersed in this mixture for about five minutes, and kept constantly in movement. The drying should be effected quickly at a temperature of about 75 deg. F.

A plate or film sensitised by this formula is panchromatic. In operation, one such panchromatic plate may be superimposed with a non-panchromatic plate, such as are already on the market, or two panchromatic plates, whereof one or both may be sensitised according to this formula are employed. The two plates are preferably put with the sensitised surfaces face to face, and may be exposed in any ordinary camera. If a non-panchromatic plate is used, this is preferably placed on the lens side of the panchromatic plate.

The two plates thus superimposed are exposed simultaneously, and the first plate cuts out a certain amount of colour from the second plate, so that the resulting two negatives represent different colour-values, and this difference is made greater by use of the special sensitiser described than is possible with two panchromatic plates, such as are at present obtainable, or one of such known panchromatic plates and a non-panchromatic plate.

The negatives are developed, and from each a positive print is made, one of which may be on opaque paper, and the other on transparent material, such as celluloid. These prints are then toned up to different colours, one, say, to an orange-pink tint and the other to a blue; the orange-pink would be employed for the positive, which is produced from the negative that was nearest the lens.

The marked difference of colour-values obtained, owing to the use of the special sensitiser described, leaves room for considerable manipulation of the prints, so that the depth of colour of either may be deepened as required to obtain a proper balance according to the subject in hand. This balance can only, of course, be judged by the operator for each subject, and will depend largely upon individual taste, but the fact that a large difference of colour-value is obtained by means of this invention in the two positives leaves scope for the desired manipulation.

For quick work the two panchromatic plates prepared with the special sensitiser given above is preferred.

If one print is on paper and the other on a transparent material the transparent print will be afterwards superimposed on the opaque print, and the two may then be mounted in any desired manner. With practice, a coloured photograph having considerable resemblance to Nature can thus be obtained.

Although plates have been referred to, obviously films may be

employed, and also the finished product may be made as a transparency by utilising transparent material for both prints.

The invention may be applied to cinema films, the celluloid portion of which may be of ordinary manufacture, but the sensitising material for one or both of the films must be made according to this invention. The two films can then be run simultaneously through the camera, and the subsequent treatment will be the same as has been already described with reference to plates, except that the final product will be a transparency.

Instead of toning the final product to different colours, the film may be stained the desired colours on opposite sides, though for the production of ordinary coloured photographs the process at first described must be used. For cinematograph work the staining is possible because of the persistence of vision and the strong light behind the film.

Where two panchromatic plates, sensitised according to this invention, are employed, the colour-values are still more widely different, owing to the amount of colour which is stopped by the plate nearest the lens, and this is sometimes an advantage, as it enhances the ease with which the strength of the different tints can be adjusted one to the other.—William Friese-Greene, 106, New Bond Street, London, W.1, and Frank Garrett, 15, Dorset Street, Salisbury Square, London, E.C.4.

Trade Names and Marks.**APPLICATIONS FOR REGISTRATION.**

FIGURA.—No. 393,582. Photographic paper. Paget Prize Plate Co., Ltd., 132, St. Albans Road, Watford, photographic plate and paper manufacturers. July 24, 1919.

New Materials, &c.**Tonitol Re-toning Solution. Made by the Hounslow Research Laboratory, 5, Bell Road, Hounslow, Midd. esex.**

THIS preparation is one for the further toning of prints toned to a sepia by the bleach-and-sulphide or hypo-alum method. It is a clear and colourless liquid of faint odour, and for use is simply mixed with five times its bulk of water. This diluted working bath has a slight though quite positive effect on sepia-toned prints. Its effect may, perhaps, be best described by saying that the reddishness of a sepia print is removed and the colour converted into one somewhat less pronounced, and to many tastes very much more pleasant. We have tried the effect of the solution upon a number of prints, and are certainly of opinion that Tonitol can render a real service to users of the sepia-toning process. The sepia prints require an immersion of only a minute or two in the working bath, and apparently the diluted Tonitol may be used on a very large number of prints without losing its re-toning powers. Most people, we think, will prefer the tone which it yields to the average original result by bleaching and sulphiding, so that photographers generally who may wish for some novelty in the colour of their prints, or experience difficulty in getting regular results by sulphide toning, will be well advised to give Tonitol a trial. The preparation is supplied in 6-oz. bottles, price 3s. 9d. each.

Hard-grade Press Bromide Paper. Made by Criterion. Ltd., Stechford, Birmingham.

A new introduction of the Criterion Company, specially for Press photographers, will be accorded a particularly warm welcome at the present time of year, when many negatives are deficient in quality through the hopeless conditions of lighting under which they are taken. The new grade of paper is one yielding a considerable extra degree of contrast; its properties in this respect approach the vigour and brilliancy of gaslight paper, whilst retaining the speed of bromide and the facility of standing forced development without the slightest liability to stain. These are features which for a great deal of current work in Press photography are of much practical value. In other respects, such as its non-stress quality and freedom from mechanical defects and chemical spots, the paper maintains the high reputation of its makers. It is obtainable as white and as mauve, both of glossy surface.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, DECEMBER 15.

South London Photographic Society. The December Competitions: I.—Lecturette Competition. II.—Excursion Slides. III.—"London" Competition.
Dewsbury Photographic Society. "Odds and Ends for Beginners." Councillor F. Newsom.
Willesden Photographic Society. "Straight Photography." T. H. B. Scott.
Bradford Photographic Society. "A Tramp in Teesdale." J. Kaye.
Kidderminster and District Photographic Society. "Mounting." W. H. West.

TUESDAY, DECEMBER 16.

Royal Photographic Society. Technical Meeting. "Fancy Lighting in Portraiture." N. E. Luboshez.
Hackney Photographic Society. Print Competition: Farmyard Scenes.
Doncaster Camera Club. Lantern Lecture: "Berwick-on-Tweed and the Adjacent 'Scott' Country." G. L. Sutcliffe.
Chelsea Photographic Society. "Westminster Abbey." F. H. Evans.
Sheffield Photographic Society. "Peeps at Nature with a Camera." Rev. B. Butler, B.J.
South Glasgow Camera Club. Lantern Slide Competition and Display of Colour Bromids.
Leeds Photographic Society. "The Magic Carpet." E. P. Dibden.
Malstone and District Photographic Society. "The Laws and its Uses." T. W. Dadd.

WEDNESDAY, DECEMBER 17.

Croydon Camera Club. "The Work and Records of the Photographic Survey and Record of Barray." J. Kenwick.
North Middlesex Photographic Society. Examples of Architectural Photography by Members.
Edinburgh Photographic Society. "Gaslight Printing Processes." J. Oliver.

Hull Photographic Society. "A Journey to Mexico and the Far West." L. Whitehead.

FRIDAY, DECEMBER 19.

Dennistoun Amateur Photographic Association. "Contact Printing." W. Foulds.
Boarhemouth Camera Club. "The Importance of Photography in the War." H. Dordao-Pyke.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held December 9, Mr. W. F. Slater in the chair.

Mr. H. F. Farmer gave a demonstration of the modification of the Ozobrome process to which he has given the name of "Carbro." Its chief difference of procedure from the Ozobrome process consists in the fact that the pigmenting and acid baths are combined into one, which Mr. Farmer calls the "sensitising" bath. The acid in this latter is supplied by the use of the acid salt, sodium bisulphate. By adopting certain definite proportions for the constituents of this sensitising bath and by taking suitable measures for its temperature and time of use, Mr. Farmer has succeeded in reducing the process to a system according to which a carbon tissue of any given colour can be immersed in the sensitising bath for a given time, and can then be depended upon to yield a good carbon print. Working formulae and instructions having been set forth at full length by Mr. Farmer in an article which appeared in the "B.J." as recently as October 10 last, it is unnecessary to repeat much of his technical discourse, but a few items may be usefully mentioned.

In working the process a useful guide is to regard the time of immersion of the tissue in the sensitising solution as the equivalent of the degree of exposure in making bromide prints. Too short immersion causes loss of detail in the high-lights of the carbon print, whilst too long a time of immersion is the cause of degraded high-lights.

The sensitiser should on no account be used below 55 degs. F. Mr. Farmer had found that below this temperature the bisulphate

became largely inert, whilst the chrome alum remained unaffected. The balance of the sensitising bath was thus upset by having it unduly cold. If, on the other hand, the temperature was much above 65 degs. the time of immersion required to be much shorter. So long as the solution could be used at any temperature between 60 and 65 degs. minor differences within these limits would be found to have no effect on the result.

Asked what kind of bromide paper he preferred, Mr. Farmer said that his favourite paper was the Wellington and Ward "Cream Crayon," which he found to be of remarkably tough substance, so that it was possible to make twenty or more "Carbro" prints from it. In reply to another question, he said that he found the surface of the bromide paper, whether matt, semi-matt or glossy, had no effect on the rendering of detail in the carbon print.

In the article in the "British Journal" to which reference has been made, Mr. Farmer included two tables of times of immersion required by various colours of carbon tissue with certain bromide papers. He explained that some papers required other times than these, but if the correct time of immersion was found with a given paper for a given colour of carbon tissue, the time for any other colour of tissue (with the same bromide paper) was then a question of simple proportion.

Asked how contrast could be modified in the carbon prints, Mr. Farmer replied that for soft results from bromide prints of somewhat great contrast more bisulphate should be added to the sensitising bath and the tissue immersed for a longer time. For contrast, the bisulphate should be omitted altogether. In order to reduce the time of immersion of the carbon tissue in the sensitising bath, the bath required to be modified by addition of more chrome alum and also more bisulphate.

In the discussion which followed, or rather was interspersed with, the demonstration, Mr. Thomas Manly, who took a seat close to the demonstration table, and showed a truly paternal interest in the process, pointed out that the combination of acid with the pigmenting chemicals in the Ozobrome process was published by himself in a manual issued before the war. Some discussion took place between him and the demonstrator as to the features in the "Carbro" process which were claimed to be new. In the course of this discussion Mr. Farmer said that while his process was based on Ozobrome, and while he had derived the use of bisulphate from Mr. Manly, he had never known the formula for the Ozobrome solution, by which no doubt he meant to say that the proportions in which bichromate bromide and ferricyanide are mixed in the Ozobrome solution had never come within his knowledge.

An interested audience followed the demonstrator in the very successful making of two prints from their respective bromides, and on the proposition of the chairman a very hearty vote of thanks was accorded to Mr. Farmer.

CROYDON CAMERA CLUB.

MR. D. SETH-SMITH, F.Z.S., a curator of the Zoological Gardens, gave a lecture, entitled "Camera Records from the Zoo," which was illustrated by many slides, all interesting, and the majority of first-rate quality.

As regards the lighting of the varied subjects, frequently were obtained striking studies bearing a strong resemblance to the complex schemes often adopted by portraitists of the modern school. In other cases one was forcibly reminded of the tricky and beautiful "back-lighting" effects frequently seen in cinematograph pictures. It is not suggested that Mr. Seth-Smith deliberately set out to secure these special effects, which probably were due to the conditions, nor that, say, the monkey-house is necessarily a suitable place for artists anxious to study unusual methods of illumination; but it is a fact that not a few of the slides were raised from mere technical excellence to things of real beauty by the wonderful play of light and shade revealed. The narrative, too, was excellent, and it was unfortunate that the wretched weather, coupled with chills and colds on the warpath, did not secure the discomfort of an overcrowded room. A most hearty vote of thanks was accorded him.

In a report of a recent lecture given by Dr. C. Atkin Swan at the Club it was stated that more than a doubt was expressed by him as to the possibility of photographing mirages. *Prima facie*, what can be seen ought to be capable of being photographed, and

Mr. G. F. Quilter, a professional photographer, of Ingatestone, bears this out by kindly sending a print which he says includes a mirage. He, however, omits to point out what parts of the print represent the actual scene before the camera and which part shows the refracted image. The print was examined by many with great interest, but none would be sure on the point, which is evidence that the mirage must be very distinct indeed. It is a pity a second exposure was not made when the mirage had vanished, as this would have afforded a ready means of comparison.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

THE second annual dinner of the Society was held in Ferguson and Forrester's Restaurant, Princes Street, Edinburgh, on the 1st inst. Mr. Edward Drummond Young, president of the Society, presided over a company of forty ladies and gentlemen, members and guests, which included Mr. Morley Fletcher, Director of the Edinburgh College of Art, and Mrs. Morley Fletcher, Mr. Wm. W. Weir, a representative from the Glasgow professional photographers, and others.—Mr. Robert Scott, in proposing the toast of "The Society," congratulated its members on the attainment of their scheme for the formation of a retouching class at the Art College, and the most satisfactory response which had been made by pupils to join the class. He was sure that under the able tuition and direction of Mr. Young and Miss Grey the pupils would derive the greatest benefit from the class which would be of immeasurable assistance to them in their future careers. Mr. Scott also spoke of the Society's proposal for the training of apprentice photographers in all branches of the art, which would materially assist to maintain the high standard and quality of the work for which Edinburgh photographers were famous. He also commended the Society to proceed with their proposal to hold a professional photographic exhibition in the near future.

Mr. Pelham S. Moffat proposed the toast of "The Guests."—Mr. Morley Fletcher, in reply, said that the number of pupils enrolled at the College for the retouching class had been a revelation to the Board. They had prepared for thirty pupils, but altogether sixty-nine had been enrolled, which showed there was a clamant need for such a class. He assured the Society that the Directors would do everything in their power to assist the Society in promoting the teaching and training of students in further branches of photography in which artistic knowledge formed the foundation. He was very much interested in the proposal to have a professional exhibition. He thought it would have a most stimulating and helpful effect.

Councillor Drummond Shiels proposed "The Ladies," and Miss Grey suitably replied. A most successful and enjoyable evening, interspersed with music, was spent.

WOOLWICH PHOTOGRAPHIC SOCIETY.—The annual general meeting took place on December 4 at the Presbyterian Church Hall, New Road, Woolwich, the new headquarters of the Society. The chair was taken by Mr. H. Furlong, and the offices were filled as follows:—President, Mr. H. Furlong; Vice-Presidents, Messrs. F. W. Machen, G. F. Meinertzhagen, C. P. Spiller, and F. Miles; Committee, the Misses Middlebrooke and D. Badcliffe, Messrs. J. R. Baker, G. R. A. Hodsoll, J. Pinches, F. J. Poulton; Treasurer, Mr. D. Collins; Financial Secretary and Consul, Mr. J. McCarthy; Librarian, Mr. C. P. Spiller; Publicity Secretaries, Miss Middlebrooke and Mr. C. P. Spiller; Lanternist, Messrs. F. G. B. Foster and G. R. A. Hodsoll; Auditors, Messrs. T. Hughesdon and Major R. J. O'Connell; Hon. Secretary, Mr. H. H. Clare, Electricity Works, Plumstead.

The Society is to be affiliated to the Royal Photographic Society and to the South-Eastern Union of Scientific Societies.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—The members of the South Suburban Photographic Society had one of the greatest surprises of their lives on the 3rd inst., for, on the President calling upon Mr. Ivor Nixon to deliver his lecture on "Make Your Own Printing Papers," there appeared at the demonstrating table a youngster who was fourteen years of age last August. With the greatest confidence and gravity this "little visitor" lectured to the greybeards and others on the making of

ferro-prussiate, plain salted, Kallitype, and phosphate papers, papers he has been experimenting with for about a year. The unconscious humour of some of the remarks contained in his somewhat lengthy "paper" was most original and refreshing, but any adverse criticism was quickly disarmed by the really excellent prints made and shown to illustrate the various coatings, tonings, etc. Master Nixon, after much experimenting, has come to the conclusion that "there is no satisfactory method of intensifying blue prints," that "the best toner for blue prints is the catechu," but "with great care pleasing tones may be obtained by bleaching in weak ammonia and darkening in gallic acid." Toning blue prints, however, was a task not recommended. Although the blue prints were so good, the young lecturer was at his best when dealing with plain salted papers, a branch of work he appears to have thoroughly mastered. The quality of the prints was exceptionally high and the tones exquisite, particularly those obtained by means of the gold and soda phosphate bath. The somewhat complicated Kallitype process frightened not this youthful experimentalist, who tackled it and investigated all the little by-ways with the greatest enthusiasm, and the prints he showed were the most perfect examples ever seen at the club, the range of colours being particularly wide. Standard formulæ, as may be found in text books, were used, though the lad confessed to making a few minor alterations in some; not, however, of sufficient importance to be chronicled. All the chemicals necessary for the making of the four papers named could, he said, be obtained from Towson and Mercer, 34, Camomile Street, London, E.C. Master Nixon was not quite so successful with his phosphate paper, but he is certain to master the process in time, as he has done the other papers named. At the moment, however, he is busy simplifying the art of making dry-plates, and the members are looking forward to another instructive lecture by the youth on plate making. For one so young, the lecturer appears to have a particularly good knowledge of photographic chemistry, and his début as a lecturer, as well as an amateur maker of sensitive papers, can be written down as a big success.

News and Notes.

J. F. SHEW AND CO.—We learn that Mr. Albert J. Garrad, formerly manager of Messrs. J. F. Shew and Co., is shortly restarting business under the title of J. F. Shew and Co., at 21, Bartlett's Buildings, Holborn Circus, London, E.C.1. It is hoped to have the business in working order early in 1920, with a full range of cameras which will be improvements upon the regular well-known Shew patterns, and in which the Shew Press cameras will be a notable feature. For the present inquiries should be sent to the temporary address, 9 and 10, Thavies Inn, Holborn Circus, London, E.C.1.

FIFTY THOUSAND PHOTOGRAPHS PER SECOND!—A Reuter report from Paris to the effect that two French experimenters, MM. Abrahams and Bloch, had devised an apparatus for taking photographs at the rate of 50,000 per second (according to other reports, 500) has aroused some interesting versions in the lay press, from which it appears that the system consists in the use of a continuously moving sensitive film and a rapidly intermittent service of light such as an electric spark. The technical aspect of the invention was well discussed with the London correspondent of the "Manchester Guardian" by Mr. S. J. Cox, who is the joint inventor with Mr. H. Workman of the Cinephrome (Ltd.) Camera. Mr. Cox pointed out that the achievement was really a development of an apparatus invented by M. Lucien Bull, of Paris, in 1904. He did not doubt the statement that 500 photographs could be taken in a second, but for practical purposes the invention had very important limitations. There were two methods of taking high-speed photographs. Under the spark system the film was moving continuously and the illuminating point was intermittent, while the reverse was the case in connection with the method under which they had been working in London, for the film moved intermittently and the light was continuous, enabling about 250 photographs to be taken in a second. A disadvantage of the spark method was that the photographs were limited to a very small surface, such as a fly crossing a 4 or 6 in. circle, because the only source of illumination was from an electric spark thrown

through a condenser, the object photographed being between the condenser and the camera.

Another important disadvantage was that the object to be photographed would have to be taken to the laboratory. Where the film moved intermittently the camera can be taken out into the open, and the object to be photographed is in the whole field of vision in exactly the same manner as an ordinary cinema. By this method eleven pictures had been obtained of the firing of a howitzer between the explosion of the fuse and the shell leaving the muzzle. In addition they had taken 160 to 200 pictures of a single complete step of a man walking at the rate of four miles an hour.

Very useful photographs have also been taken of surgical operations, especially in cases where the surgeon has been compelled to move so quickly that the actual operation was barely visible to the students gathering round.

On the other hand, a usefulness for the "spark" method could be found in taking small objects, such as bullets or insects, when the exposure would have to be something like a hundred-thousandth part of a second. The bullet could then be shown in its flight.

From the medical point of view, he added, the spark method cannot mean a revolution in experimental science, because, so far as he was aware, the resources of the cameras already existing had not been taxed. Unless there was something not disclosed at the tests he did not think that the new system would mean anything like a revolution in connection with such experiments.

Commercial & Legal Intelligence.

NEW COMPANIES.

DEVELOPERS, LTD.—This private company was registered on December 2 with a capital of £10,000 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in photographic dry-plates, papers, and films for photographic and other purposes, etc. The subscribers (each with one share) are:—H. J. Wakefield, 17, Burghley Road, Leytonstone, N.E., clerk; E. T. Church, 33, Solon New Road Clapham, S.W.4, clerk. The subscribers are to appoint the first directors.

HARCO, LTD.—This private company was registered on November 23 with a capital of £5,000 in £1 shares (2,000 pref.). Objects: To take over the business of a photographic dealer carried on by P. G. Hunt at 86, Milton Road, Hanwell, as "J. E. Hart and Co. (London)." The subscribers (each with one share) are: P. G. Hunt, 86, Milton Road, Hanwell, photographic dealer, J. E. Hunt, 4, Willcott Road, Acton Hill, W.3, photographer. The first directors are: P. G. Hunt and J. E. Hunt (both permanent). Registered office: 86, Milton Road, Hanwell, Middlesex.

THE DEVELOPMENT OF LANTERN SLIDES.

To the Editors

Gentlemen,—Will you permit me to correct an inaccuracy in the report of Mr. Lisett's lecture at the R.P.S.?

I did not say I "knew of no way of working, except by examining the transparency." On the contrary, I advocated, first, the advisability of ensuring correct exposure by paying attention to the density of the negative, the strength of the illumination, and the speed of the lantern plate; and, secondly, the controlling of the degree of development by the use of the Watkins factorial method.—Yours faithfully,

W. D. FERGUSON.

48, Compayne Gardens, N.W.6

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. C.—The makers of the Jay Nay specialities are Messrs. J. and A. Wilkinson, 60, St. Oswald Street, Manchester.

W. H.—By far the most usual method in the trade is by stripping from glass, the glass being cleaned either with French chalk or with one of the glazing preparations, such as ox-gall.

P. A. G.—Printer's engineers, such as Hughes and Kimber, 9, Gough Square, or Furnival and Co., 102, Clerkenwell Road would supply embossing or blocking presses such as you require.

E. B.—Apart from the little Panoram Kodak, the only two panoram cameras are the Cirkut of Kodak and the Al Vista of Houghton's. Both of these are of American make, and it is therefore doubtful if you can get them now.

F. D.—A total c.p. of 6,000 is enough for all ordinary purposes. We should, however, prefer six 1,000 c.p. to three 2,000 c.p., as the light could be better distributed. We do not, however, know what form of reflector you are fitting, so cannot advise on fixing diffusers.

T. J. G.—You will find the half-watt lamps quite satisfactory. If you write to the General Electric Co., Ltd., 67, Queen Victoria Street, London, E.C., they will send you a booklet giving full particulars of the various fittings from which you can select those best suited to your studio.

W. J.—Your prints are evidently under-exposed. You must bring your lamps nearer to the sitter; 2,000 c.p. is hardly enough for short exposures. Your plates, too, are rather slow; try a 400 H. and D. plate, such as the Ilford Zenith. You do not give aperture of lens; for such work it should not be less than $f/6$.

B. and S.—If the business was established before February, 1918, it is not a new business within the meaning of the Order, and therefore no licence is necessary. There is nothing in the order which causes an old business to become a new one, simply from the fact that the original proprietor has joined himself in partnership with someone else.

H. G.—For the starting of any new business, either by a British subject or by an alien, a licence is required. You had better apply for information to the Secretary, New Retail Businesses (Licensing) Order, 99, Queen's Gate, South Kensington, W. A photographic studio, as regards the parts of the premises where the public are received, comes under the Shops Act.

E. A.—The lens you describe is an ordinary or Petzval portrait lens, probably of French make, issued by the Photographic Artists' Co-operative Supply Association, which carried on business in the late '70's. Two lenses marked No. 3 were issued: one $3\frac{1}{2}$ ins. in diameter was priced at £5 15s. 6d. and the other $4\frac{1}{2}$ ins. in diameter was £19 16s. Both were listed for cabinet size. We can give no idea of their present value.

A. V. C.—(1) The licensing office for the Cambridge area is at 80, Westbourne Terrace, Paddington. (2) We advise you to use the pyro-soda formula recommended by the makers of the plates you are using for dish development, but making it up with, say, three times the quantity of water and using twice the quantity of sulphite or metabisulphite. This will probably give you a tank developer yielding satisfactory average density in about twenty minutes, but you can best discover for yourself whether you require to take more or less water than indicated above by trying the developer on a few plates.

J. C.—We think that in the event of it coming to a County Court summons you would succeed in recovering such a charge as 10s. 6d. for your attendance in the effort to carry out the order. The doubtful thing is that apparently the order was a verbal one. If you had an order in writing we should feel more confidence in advising you as to the view which a County Court judge would take. But where the evidence on both sides is wholly verbal, common justice is apt to go astray.

W. H.—A burnisher is only suitable for prints on glossy paper which have been wet mounted. The gas must be lighted inside the hollow roller and the temperature allowed to reach that of an ordinary laundry iron. If too hot the prints will burn or blister; if too cold there will be no gloss. The prints should not be bone dry, and should be placed face down on the hot roller, then fed through two or three times, curving the ends upwards as they pass through. When cool they will be flat. The roller must be kept brightly polished and free from scratches.

T. L.—There is unfortunately no hook which we can recommend to a photographer of your experience. There was a very excellent book issued by Mr. Batsford some years ago called "Art Principles in Photography." We acted as agents for Batsfords and sold a fair number of them, but the book is now out of print. You could perhaps get a copy by inserting a small advertisement for it. A book which perhaps you might study with advantage from the art point of view is one called "The Appeal of the Picture," by F. C. Tilney, published by Messrs. Dent. It deals about as much with landscape as with portraiture, but is a very excellent book from the art standpoint.

E. S.—The question you ask has not, so far as we know, been generally decided under the Retail Businesses (Licensing) Order. Generally speaking, the object of the Order is to protect demobilised men like yourself, but it is conceivable that your caravan business would operate harmfully in certain places upon ex-Service men who had returned and started in business in a small town or village. Therefore we imagine that your case would be decided on its merits, and with reference to the scope of your journeys. If these are in Leicestershire you had better write for particulars to the office which deals with this district—namely that at 80, Westbourne Terrace, Paddington.

P. H.—1. The addition of a photographic portrait business to a mantle business is the starting of a new business according to the Retail Businesses (Licensing) Order, administered by the Ministry of Labour. 2. The application for a licence could be refused, but we do not know the precise reasons by which the administrators of the Order are guided. The main one presumably is that the new business is being started upon a new beat, where a man who has served in the Army, or is still serving there, previously carried on his trade. 3. We think you are entitled to a week's notice or a week's salary in lieu of notice. The fact that a licence has or has not been obtained has nothing to do with you. The employer must take the liability for that.

E. G. B.—The print must be made on very thin paper, and for this reason albumenized paper was formerly used. If P.O.P. is used, it should be hardened in formaline to prevent the film from melting. A solution of gelatine, say 1 oz. in 50 of water, is made, and while quite warm is poured into a dish of sufficient depth to cover both glass and print, which should be immersed for two or three minutes till quite warm. The print is pressed into contact with the glass with the fingers, and the surplus gelatine wiped off after the glass is nearly cold. In place of warm gelatine a cold solution, made of gum tragacanth, 3 parts; gum arabic, 10 parts; water, 50 parts, may be used in the same way. The print must be soaked until very limp.

R. D.—The only possible light is flashlight, a serviceable outfit for which is obtainable from Messrs. Johnson and Sons, Ltd., 23, Cross Street, Finsbury, London, E.C. A machine for generating electric current would weigh something in the neighbourhood of half a ton. For printing and enlarging machines apply to Mr. G. S. Moore, 69-73, Denmark Hill, Camberwell, London, S.E.5, or Messrs. Brodrick, Ltd., 50, High Street, Charing Cross Road, W.C.2. Combined developing and fixing is no good for this work. Use a quick-acting developer and a strong acid fixing bath. There

is no book on the subject, although articles on putting work through with speed have been published in the "B.J." from time to time, for example, on May 21, 1915, and December 3, 1915. Both these will be useful to you. Price 4½d. each post free from our publishers.

G. S.—(1) The lamps are made by Blanchard Lamps, Limited, 151, Farringdon Road, London, E.C. For short exposures you would want at least two of the high-power lamps, which the firm rates, I think, at about 1,000 c.p., and supplies, so far as we recollect, at about £20. This was the price two or three years ago. We think the lamps would last for a good many years. The chief drawback to them is the amount of heat they give out, also the rather great over-all length. Both of these features make it rather difficult to use the lamps in a small and particularly a low studio. (2) The Licensing Order is still in force in regard to businesses started since February, 1918. There is no office at Derby. Applications relating to Derbyshire should be addressed to New Arts Buildings, Liverpool; those in respect to places in Nottinghamshire, to Harewood Barracks, Woodhouse Lane, Leeds.

COPYRIGHT.—I have a photograph of Belvoir Castle, given me some years ago. It has no name on it, and I do not know by whom it was taken, although I imagine it is the work of a professional photographer. I would like to have a negative made from it, so that I could make a few bromide enlargements. Do you consider me free to do this without infringing copyright? In order to maintain copyright, is it not necessary to intimate on the print that the same has been protected?—BELVOIR.

It is almost certain that copyright exists in the work, in which case you will be committing a legal infringement by copying it in any shape or form. It is not necessary that the word "Copyright" should appear upon photographs which enjoy copyright protection. At the same time, the reproduction which you appear to contemplate is on a small scale, and if it came to the knowledge of the photographer would scarcely be considered worth while troubling about—at any rate, if the prints are made simply for your personal use and not in any way for trade purposes or for reproduction in any periodical.

The British Journal of Photography.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will be placed there whenever its regular position is required for notices relating to the forthcoming "B.J. Almanac."

A Book Within a Book.

The forthcoming "British Journal Almanac" is more than a collection of the hints, expedients, and formulæ of the year, valuable as this *résumé* of the year's progress is to everyone doing practical photographic work.

The 1920 "Almanac" will contain also within its covers a little book which is written specially for the beginner in photography, yet will be found deserving of the attention even of those of wider experience.

This is the section of the "Almanac" entitled "Beginners' Failures in Photography." In it the defects which can arise in the making of negatives and prints are considered according to a systematic plan. The basis of the arrangement is that the defect is described as specifically as can be done in words, and the causes and remedies (or preventives) dealt with in a full yet simple way.

In this article of over fifty pages, chief consideration is given to defects in negatives from thinness, flatness, hardness, excessive density, stain, fog and like defects.

There is a good deal to be said for arranging instruction on these lines, for, apparently, many a beginner will gather experience in the proper carrying out of intensification or reduction when the process is prescribed as the cure for a defective negative who will not take the trouble to read a text-book which has intensification or reduction for its subject.

The article deals also with the causes of various kinds of spots, bands, lines, patches, and other markings on negatives, and serves to show the reader by what exceedingly simple causes some of the most mystifying defects are produced.

The concluding chapters of this "little book" deal with bromide and gaslight printing, making self-toning prints, mounting, and dry-mounting—all "according to the plan."

EX CATHEDRA.

Threepence on Jan. 2. Beginning with the issue of January 2 next the price of "The British Journal of Photography" will be threepence. The increase of price has, unfortunately, become necessary through successive increases in the cost of printing, coupled with the stabilising of a high price for paper. Printing charges, successive increases in which came into force during the war, have during the last few months advanced by a further very substantial amount. As regards paper, while it was possible during the latter part of the war to compensate for the greatly increased cost of paper by a somewhat lesser number of pages in each issue of the "Journal," such a course is no longer possible without a departure from our policy of making the "B.J." representative of all that makes for progress and advancement in every department of photography. Our publishers therefore have no alternative but that of increasing the price charged for the paper to threepence, an advance of 50 per cent., which may be thought to be a very moderate one indeed when set against the threefold price now charged for both paper and printing.

* * *

Shading.

It is a matter of some difficulty when shading a portion of a negative when printing to prevent a more or less hard outline where the shaded part merges with the rest of the picture. When printing-out paper is employed the usual and the more satisfactory method of shading during the exposure is by the use of a piece of card moved backwards and forwards over the part of the negative that it is desired to retard; yet this plan tends to give hard edges. A good way to avoid this defect is to cut a series of fairly deep saw-like segments into the card at its edge, bending these in an upward and downward direction alternately. This idea is based upon the old-fashioned paper mask or vignette used years ago, the edges of which were cut in the same fashion as the teeth of a saw. It will be found that if the plan mentioned above is carried out and the printing frame kept in fairly weak light during the exposure a very much softer result will be secured and probably one that will give no indication that shading has been done. With development papers it will also serve, providing the printing light is well diffused and the card kept in motion. Of course, the idea cannot be carried out with the printing machines and boxes so much used to-day. If a negative needs local shading the printing frame should be employed, when the above method will be found to repay a trial.

* * *

The Index Habit.

With next week's issue of the "British Journal" will be presented, unless nothing unforeseen intervenes, the index to the present 1919 volume. We take some considerable interest in the compilation of the index to the "B.J." and think we may claim for it

that it provides a very clear and commonsense guide to the varied contents of the volume. In our own office work, chiefly of replying to correspondents, we constantly have to refer to the indexes of past volumes and are often prompted to wish that a greater number of our querists would preserve the indexes. Many people, we can understand, cannot afford the shelf-room for the storage of bound volumes of the "Journal," but if they are under any frequent necessity of addressing queries to us they would save both themselves and us a good deal of trouble by making use of the indexes. A fair proportion of the questions which reach us consist of requests for some formula or prescription which "was given in an article some months ago." Such queries afford a wide field for search, whereas if the questioner would take a glance over the indexes he could probably spot with fair certainty at any rate the two or three articles in one or other of which is to be found what he is seeking. As will be seen from the index to the present volume, now almost ready for publication, no attempt is made to classify the contents, but the simplest A B C arrangement is adopted.

* * *

Light-Control.

A great many photographers rely almost entirely upon the studio blinds or curtains for controlling the lighting, and seem to be oblivious to the utility of portable screens for locally shading such portions of the subject as may need it. Frequently the drapery and the face require different degrees of illumination, and very often one or the other is sacrificed. The ordinary white head screen is now pretty widely used, but it is not the best thing when it is desired to tone down a glaring white dress so that it will take its proper place in the scale of tones. For this a similar screen covered with black gauze will be found much better, as it subdues without scattering the light. "On the other side," a rather large circular screen covered with very thin tracing cloth, with a circular opening a foot or fifteen inches across, is frequently used to secure a strong illumination of the head and a subdued one of the drapery. Unfortunately, it is almost impossible to buy the ordinary pattern of head screen at present, but anyone with a little mechanical skill can make a fair substitute with a disused head rest and a few feet of stout wire.

* * *

Time is Money.

It is usual in trades where labour forms the largest item in producing an article to keep a careful record of the time taken on each of the stages of production, so that when the job has to be charged up there is no uncertainty as to the cost under this heading. This practice does not, we believe,

obtain to any great extent in photographic establishments, although we know of one or two where it is carried out with very satisfactory results. Now that wages have increased all round, it is very necessary for photographers to be certain that their work is not costing more than they obtain for it, or, at all events, more than it should do. This applies more to wholesale trade and commercial firms than to portraitists, as the latter charge on a totally different basis, and it is only a question of a smaller profit instead of actual loss. It is a curious fact that the worst offender is usually the single-handed worker, who very often does not get for a completed job as much as he would have to pay a competent assistant in wages alone for doing the whole work. We recently went into this matter over an order for groups taken at a distance from the studio, and found that the time occupied, at eightpence per hour, amounted to about 20 per cent. more than the total amount charged. He charged more for the next similar job.

* * *

Paper Negatives.

When enlarged negatives have to be made from faded and granular originals, there is often an advantage in using either the special negative paper or even ordinary smooth bromide paper, instead of the usual glass plate, for not only is the cost much less, but the necessary working up is much more easily effected. As everybody who has worked up an enlargement knows, no medium or other preparation of the surface is necessary, and blacklead, chalk, or water-colour may be used with equal facility on either side. It is usually recommended to oil or wax the paper to reduce the time needed for printing, but, in our experience, this causes the grain of the paper to become more noticeable, and we have found it better to leave the paper in its ordinary state. If ordinary paper is chosen, it should not have a baryta substratum, but should leave the emulsion coated direct upon the base. We have found the Ilford smooth, rapid grade excellent for this purpose. About double the exposure necessary for an ordinary enlargement should be given when enlarging from a small transparency, while the exposure when making the negative direct from a small print should be ascertained by means of a small trial strip.

* * *

"Rembrandt" Lighting.

One of the difficulties encountered in making portraits in the "Rembrandt," or, as the Americans more correctly call it, "edge-lighting," style is the exclusion of unwanted light from the lens. It is a common experience to find a general fog all over the negative, and many operators have come to consider this as inevitable, while others, by means of lens

SUMMARY.

The Christmas Holidays. Will correspondents and advertisers kindly note that next week's "B.J." will be closed for press at noon on Monday next, December 22.

Beginning with the issue of January 2 next the price of the "British Journal" will be threepence weekly. (P. 733.)

The Index to the 1919 volume of the "British Journal" will be presented as a Supplement to next week's issue.

In a contributed article Mr. D. Charles describes a simple device for obtaining accurate reproductions of scale in the copying of originals in the camera for reproduction by one or other of the true-to-scale processes. (P. 736.)

In an article contributed to our contemporary "Camera Craft" Mr. G. W. Greene describes at length the outfit found most efficient for the development and printing of amateurs' film negatives. (P. 740.)

In his article this week "Practicus" deals with the making of reproduced negatives, and has a number of hints to give on the method which usually it is most advisable to adopt. (P. 739.)

Some notes on the relative merits and drawbacks of the different processes for the toning of bromides will perhaps add to the information of those who have used only the bleach-and-sulphide method. (P. 743.)

In a leading article we give working instructions in the neat introduction of titles and other lettering in view negatives. (P. 735.)

Double-pose portraits, enlarging with metal-filament lamps, supplementary lenses, spots on blotting boards, and elementary properties of lenses are the subjects of brief replies to correspondents. (P. 747.)

A firm undertaking aerial photography has announced that over a quarter of a million pictures have been made and sold in a few months. (P. 747.)

An Australian correspondent warns against the after-effects of formaline when used in the tropics as a means of hardening the gelatine films of negatives. (P. 747.)

Details of a rotary print-drying machine are given in a recent specification. (P. 744.)

A shading screen of black gauze is a very useful accessory in the studio, particularly when it is wished to reduce the tone of a white dress. (P. 734.)

The photographer's own labour is very often grossly undercharged in fixing the price of work done away from the studio. (P. 734.)

Smooth bromide paper is an excellent sensitive material for the copying of many originals. There is no need to oil or wax it for printing. (P. 734.)

hoods and other more clumsy devices, have managed to reduce it to a considerable extent. We have lately seen a very simple device, which almost entirely does away with the trouble, and has the advantage of remaining in position, no matter how the camera is moved. It consists of a dark card about a foot square, having a cabinet-sized opening cut in the centre. This is fixed in the ordinary camera vignetter in place of the serrated card usually employed. The card is adjusted so as to darken all the focussing screen, except the portion actually occupied by the image, this being easily done by temporarily removing the ordinary carte or cabinet mask from the camera back and manipulating the vignette till only the size of the plate to be used is uncovered. It is obvious that as the lens cannot see the window or other source of light the fogging effect is practically eliminated.

TITLES IN VIEW NEGATIVES.

THE lettering of the negatives which a photographer uses for his production of view postcards appears to be one of those operations which is very largely done in an amateurish way. Were it not that we are constantly in receipt of queries as to the best way of doing it, we should have thought that the professional method of setting about it was familiar to all our readers. On the contrary, it appears, from many view postcards which come into our hands as examples of defects of printing or toning, that many small publishers of view cards do not seem to realise the unsightliness of the lettering which often is a disfigurement of really good photography. It cannot be expected that the locally produced postcard can compete with that of the large postcard publisher if attention is not given to every item of detail, including this of the lettering. It may therefore be a service to many others of our readers than those who have specifically put the question to us if we refer once again to the method of providing titles on view negatives by which the lettering can be done in a workmanlike manner.

Briefly, the method consists in photographing the words of the title (in the form of a proof from type-setting or of an original hand-drawn on a considerably larger scale) down to the required size, and transferring, by stripping, to the view negative. Naturally, a much neater result is obtained by setting up the titles in type and taking a good proof from the type matter. If the cost of sufficient type for this purpose cannot be incurred, or if a local printer cannot be commissioned to do this part of the work, a very fair substitute for it is available in the method of drawing the printed characters for the title upon a considerably enlarged scale—say, five or ten times the size which the letters are required to be in the negative. Any roughness of outline due to the hand method of producing the original thus largely disappears in the small scale reproduction: good shape of the letters themselves and conformity to a given style of type may readily be secured by making up a set of sufficiently large letters from a printer's or type-founder's catalogue and tracing these, when evolving the title, upon engineers' tracing cloth, which is then backed up with white paper for photographing.

In making the negative it is customary to photograph a fair number of titles together. The best plate for the purpose is one of the "process" or "photo-mechanical" kind, with which clear lines (the letters), in conjunction with opacity of the ground, are readily obtained with an ordinary pyro-soda or hydroquinone developer. The negative having been developed, fixed, washed, and dried, the film is cut through to the glass with the aid of a straight-edge and a sharp penknife, so as to divide the different titles into separate sections of

emulsion film. It is then a very simple matter to treat the whole negative by a stripping process such as that the formula for which is given in the "Almanac." After treatment with the hydrofluoric mixture, each narrow band of film containing a single title can be readily raised, detached, and transferred to the view negative. Before applying the title strip to the latter it is usual to cut out a strip of the emulsion film with a sharp penknife so as to provide a clear space for the reception of the strip bearing the title. This bared glass is painted over with a little weak gum solution, to secure the adhesion of the title film. This having been applied and left to dry, the negative is then ready for masking, the customary method for which is first to mark off the subjects in Indian ink with a drawing pen and straight-edge. The further blocking-out is then done with any good mixture, such as Vanguard "Photopake," in applying which the opaque is taken up as close as convenient to the transferred letters. This method of masking the negative and of inserting the title just outside the outline of the mask gives a much better effect than any attempt to introduce the title upon a portion of the negative representing part of the subject itself. It presupposes, of course, that a negative of half-plate size is available, although at a pinch it is applicable also to those of postcards ($5\frac{1}{2} \times 3\frac{1}{2}$ size).

If, on the other hand, the photographer wishes to avoid the trouble of this masking, which certainly imposes a considerable degree of accuracy in printing the cards in order to obtain a uniformly wide white margin round the picture, the strip method may equally be employed, although it is then usually preferable to use not the original title negative, but a positive printed from it on to another process plate. This gives, of course, black letters on a clear ground, and usually in most landscape subjects a place can be found for it where it will print satisfactorily, or if the negative is one which is unsuitable in this respect the use of a little strong Farmer's reducer or iodine-cyanide mixture on a fine camel-hair brush will provide the requisite clear space in the landscape negative.

The above, or, rather, the form first described, is the method generally adopted by publishers of view postcards on the large commercial scale, although variations of it, in some cases altogether non-photographic, have been employed. For example, Mr. G. T. Harris, of Sidmouth, himself a publisher of view postcards on a considerable scale, described at length, some years ago, in these pages ("B.J.," April 19, 1912) a variation of the process in which the titles are set up in type, impressions taken directly from them in a small printing press, and fine electrotyper's plumbago immediately dusted over in order to give greater opacity to the ink impression. This is a method, of course, for insertion of the title upon the subject portion of the view negative, the letters printing in white against the dark or medium tone of the photograph.

POSTCARDS OF THE CARPENTIER-BECKETT FIGHT.—Messrs. Lilywhite, Ltd., Dunkirk Mills, West End, Halifax, send us a complete sample set of their postcard reproductions (from "Daily Mirror" photographs) of the recent famous boxing event. The series includes twenty-four cards, which, taken altogether, form a very effective record of the short and rapid phases of the fight. Messrs. Lilywhite seem to have received a measure of inspiration from Carpentier's rapid action, for they point out that they have beaten all their own records in rapid production by producing 24,000 of the cards between the receipt of the negatives on December 11 and the morning of Sunday, December 14. By the end of the present week they will have about a quarter of a million of the cards ready for despatch.

ENLARGING AND REDUCING IN TRUE-TO-SCALE PROCESSES.

Altho' the term "true-to-scale" usually is employed to denote one particular method of reproducing line drawings, tracings, plans, etc., that known as the Ordoverax process, there are other printing methods in quite general use to which the definition of true to scale can be applied with at least equal veracity. In the case of engineers' or architects' tracings, as well as in the reproduction of maps, it is perfectly obvious that the accuracy of the scale in any copy is absolutely essential, so that measurements may be read off in any desired detail just as correctly as in the original drawing.

The Ordoverax process referred to comprises first the making of a ferro-prussiate print from the tracing, laying this blue-print (without any washing) down on to a prepared gelatine surface and pulling it off again, whereupon the jelly is rolled up with greasy ink. The latter adheres to the lines, and pulls are made on plain paper. The latter is necessarily of fairly stout substance, and the moisture absorbed from the gelatine is seldom sufficient to cause it to expand to any appreciable extent, so that the pulls are reasonably identical with the original. It is pretty obvious, however, that it is not a process which lends itself to the production of copies on any other scale than that of the original; but it is not a very difficult matter, as I propose to show, to make an accurately enlarged or reduced copy of the original tracing, from which the process can be carried on almost in the usual way.

In addition to this process there are two other printing processes, worked by lithographers, which are just as much entitled to be described as true to scale, and have this advantage: that, whereas the jelly process will give only small editions up to fifty from one blue-print, the litho. plate made on zinc will yield thousands, and is, in fact, much used in the printing of maps, in which work accurate scale is absolutely a *sine qua non*. The first of these two processes is that known as "Vandyke," in which the sensitised zinc is printed in contact with the original tracing or drawing in a box pressure-frame, and is subsequently washed and inked up, when it is ready for the litho. printer. This process can be worked from drawings on quite thick paper provided that the lines are opaque and that a long exposure to daylight can be given. The making of a plate to a different scale from that of the original may frequently be desirable, and I shall show how this may be done without loss of accuracy in the same manner as for the ferro-prussiate process.

The other method referred to is that in which the zinc plate is printed in contact with a reversed line negative, just as in block-making, but etched and inked up to suit the litho. printer. Obviously the negative can be made to any desired scale. To obtain a standard of great precision in copying in the camera appears to have been left entirely to methods of trial-and-error and rule-of-thumb, even in establishments where one would expect nothing short of the very finest possible work. After some experiment I have succeeded in evolving a method of measuring the image on the ground-glass with ease. The plan involves a little trouble to start with, but once fixed up there is nothing at all to go wrong, and the correct adjustment of the camera becomes almost child's play. What calculation there is is very elementary arithmetic indeed, and has nothing to do with such factors as the focal length of the lens or ratio of enlargement or reduction. I have found these factors more often than not to contain a fraction which only confuses and complicates matters. The average operator appears to hate anything in the nature of calculations, and although it has not been possible to eliminate this feature altogether, it has been reduced to absurdly small dimensions. I have ruled out methods involving the calibration of the base-board calculated

on the focus of the lens, partly for the reason suggested above, and partly because it is impracticable to work on that idea unless one knows the focal length of the lens to a very minute degree of accuracy, besides which a fresh table has to be worked out for each instrument. The method described below will work with any camera or lens at any time, and cannot be affected in its accuracy by such a cause as shrinkage or expansion of the original under climatic conditions, or by the use of colour filters, features that render tabulated methods useless.

Bromide or Gaslight Print as Original.

To take the former processes first, that is those printed from the positive tracing, it is not generally known that a bromide print reproduced in any size can be printed from with almost the same ease as the original drawing. There are, however, certain difficulties involved in the production of a suitable print. The bromide paper is fairly opaque, of course, and requires long exposure, but this can be much

Fig. 1.

shortened by rubbing castor or linseed oil or even turps into the paper. The image being purely line work, the grain of the paper is of no account; semi-matt paper usually is more translucent than other surfaces. Another supposed objection is the wetting and drying that a bromide print necessarily receives in its production, and is thought unavoidably to introduce alteration in size. I have found, however, that if sensitive paper is well dried by leaving in a warm place for a time before exposure, and subsequently thoroughly desiccated in the same manner when the print has been made, there will be no difference that can matter in any but the very finest work, and it is scarcely probable that this method would ever be used for work of such a critically fine character. The bromide print is made from a negative-

which is copied in the camera, of course, either by enlarging or contact, according to circumstances. In enlarging, however, a line subject will thicken up almost always considerably on bromide paper when the lines are developed sufficiently dense for the purpose. So much so, in fact, that fine detail may become obscured. Even the "Press" variety of bromide paper is liable to this fault, and it is much better to make the negative quite thin, making sure that the lines are quite perfectly clear, and enlarge on to gaslight paper. This not only has the property of retaining the lines absolutely sharp even when considerably over-exposed, but actually gives a much denser deposit of black image than bromide paper will. Of course, both in copying and in enlarging, care must be taken that the apparatus is properly set up, or if all the parts are not absolutely parallel or perpendicular to one another, as the case may be, some portions of the subject may be found very much out of scale in the final result, although the detail focussed on will be correct.

Perhaps an example will make clear the procedure. Supposing the tracings or working drawings of a machine are required to be reproduced on a smaller scale than that of the originals, say one-half or less in order that prints of a less unwieldy size may be issued for general use. Obviously, it is a far quicker thing for a photographer to make a negative and a print or enlargement from it than for a draughtsman to set out the detail all over again to accurate measurements. Even if the draughtsman is called on to do the work, he can much more easily and quickly draw on a sheet of tracing-cloth laid over a photographic print. This latter method was very largely used during the war for rapid reproduction of maps in various sizes. The negative can be made to any convenient size, and accurate measurements taken on the enlarging easel. Any measuring in this method should be made over as long a line as possible rather than by any particular detail. That is to say, that even when the scale is marked, as it usually is, on the original, it is preferable to take the distance between two prominent points diagonally across the subject as a basis for measurements in order to minimise inaccuracies.

The resulting enlargement can be used either as a guide for the draughtsman or, after a little touching up here and there, as the medium for producing a blue-print for the Ordoverax process, or for making a zinc litho. plate by the Vandyko process.

Making Reversed Negatives: Three Methods.

It is, however, the method of making a negative from which to print a litho. plate that is depended on for the finest and most accurate work. Either a reversed or non-reversed negative can be used. In the latter case the image on the zinc has to be transferred and reversed, and this is seldom done without some loss of detail, which has to be made good by the litho. draughtsman, and I believe transferring tends to thicken the lines slightly, so that it is highly desirable to employ a reversed negative. There are three methods of making these. The first is to reverse the process plate in the dark-slide and the ground-glass in its frame (or make the necessary adjustment after focussing for the thickness of the plate). I do not recommend this method at all, though it has been used fairly successfully at a pinch. Unless the original to be reproduced is of the easiest possible nature, such as bold black lines on the whitest of Bristol board, it is best left alone. The objection to it is that copies from tracings and similar poor originals usually need clearing and intensifying (I am referring to dry-plate work), and by the very nature of the method any veil that may be on the lines will be next the glass, where the reducer will hardly reach it, and on intensifying the lines are found to clog up badly. Another factor to which I attribute the failure of this frequently recommended but very unsatisfactory plan is the reflection and re-reflection of light between the film and the

front surface of the glass. This form of halation is usually sufficient to veil the lines long before the ground has attained sufficient density, and matters are still further complicated by the unevenness of the emulsion on the plate preventing even action of the various solutions. This might be thought a negligible factor in line work, but it happens that its results, in the form of lines showing up thicker or thinner in various portions than they should be, are more noticeable than in almost any other branch of photography. I may seem to have dwelt on this matter rather more than its importance deserves, but I think it a good opportunity to try and kill the idea that to reverse the plate in the slide is a simple, quick, and easy mode of producing a reversed negative. It sounds like it, and that's all.

The second method is to copy through a prism. Obviously this is the best plan, but is possible only where a proper process camera is installed, and reversed negatives are produced as easily and as quickly as direct ones.

The third plan has been found in practice to work splendidly. It consists in making an Ordoverax print from the original tracing, but with this deviation: that, whereas ordinarily the necessary blue-print is made through the back of the tracing, this time the ferro-prussiate paper is printed in contact with the actual pen work. The result is a print in sharp black lines on white paper, but reversed as compared with the original tracing. This forms a very easy subject for copying *direct* in the camera on either process or wet-plate with a reversed negative as the result.

Alternative to Making a Reversed Negative.

Where neither of the two latter methods is practicable, by reason of the photographer not having access to either a process camera or an Ordoverax installation, I do not recommend the trial of the first method, i.e., reversal of the plate in the dark-slide, for reasons already sufficiently fully enlarged upon, but in place of that to make a direct (i.e., unreversed) negative, from which a glass or paper positive is printed by contact, and the latter printed on to the zinc by the Vandyke process.

A paper positive can be made, as previously described, by thoroughly drying a sheet of gaslight paper before printing it, and subsequently drying it in as nearly as possible similar conditions before printing on to the zinc. Naturally a glass positive is preferable for the very finest detail and extreme accuracy, and should be used in all cases where size does not make the cost prohibitive. The glass positive is made on a process or a special lantern plate behind the negative in a screw pressure frame, and exposed to a very small source of light held quite still at a fair distance away. The light of a match is usually enough. The emulsion side of plates is usually slightly saucer-shaped, and good contact consequently hard to secure, so that a diffused or moving source of light may weaken the finer lines.

I should like to emphasise at this point the necessity in this branch of highly-skilled photography for absolute accuracy in the construction and adjustment of the various parts of the copying installation. If the apparatus is not substantially and correctly put together the cleverest operator cannot always produce flawless results. It is neither a long nor a difficult job to test any installation as regards the rectangularity and parallelism of its parts, but it is often a matter calling for much care and patience to correct any faults that may be found.

Having now dealt fairly exhaustively with the various methods of reproducing line subjects in general use, as well as one or two variations which I believe to be very little known, I propose to describe my method of obtaining absolutely accurate scale in copies made in the camera with the greatest possible ease.

Measuring the Image on the Ground-glass.

Anyone who has ever tried measuring the image on the focussing-screen with a foot-rule knows the slow job it is, and the surprisingly great errors in results made possible by the thickness of glass between rule and image, as well as by the difficulty of keeping the end of the rule on any given point. The movement of the image during focussing adds materially to this inconvenience. The plan to be described is adaptable to any form of camera for dry or wet-plate, and involves no expense beyond a little time and careful work. All the constructional work required is some means of sliding the ground-glass laterally for a small distance, say a quarter to half an inch, or else to make a device by which a piece of glass or sheet celluloid will slide laterally in contact with the ground surface, to be workable from outside the camera.

Fig. 2.

Neither of these is needed in the case of a process camera possessing a rising or cross-front actuated from behind so that the moving image is observable on the ground-glass. There is nothing difficult about making the ground-glass to slide. The lateral movement may be introduced simply by cutting a narrow strip off one end of the glass, and, if necessary, fixing small pieces of wood or metal to support the open edges and prevent breakages (fig. 1a). Alternatively the rebate in which the ground-glass lies may be cut wider to allow of the sliding movement or the whole focussing-frame

Fig. 3.

may be arranged to move in some cases. Where this is not convenient, a fitting on the lines shown in figs. 1b and 2 can be very easily fitted. Fig. 2 shows a narrow metal frame to take a piece of glass which is fixed in position with its surface slightly raised above the edge by the simple expedient of bevelling the corners and making nicks in the metal, as shown in the diagram. Bevelling the glass is done by means of a file under water, and takes a few seconds only.

A pair of very fine lines is drawn on the ground-glass in the one case or on the sliding piece in the other, exactly vertical and 2 ins. apart. The left-hand line is to be as near as may be to the centre of the ground-glass and the other 2 ins. to the right of it. Refer again to fig. 1. The essential points of this detail are the absolute parallelism of these two lines to the edge of the ground-glass, their fineness and exact distance apart, and the ability to move this two-inch column from side to side very slightly. The only variation is in the case of a camera having a rising-front (but not a cross-front) operated from behind. In this case the lines should be horizontal instead of vertical, but the ground-glass may be fixed, as adjustment is effected by working the rising front. Before proceeding with the subject it is necessary to show how these parallel lines can be fixed to a very minute degree of accuracy, this not being so simple in small sizes as in large ones. In fig. 3 a small focussing screen is shown temporarily stuck to the centre of a larger sheet of paper or card, on which a line is drawn producing one edge of the glass and others at right-angles and parallel to it, marking the two-inch column. By working over a greater area, the degree of inaccuracy at the edges is reduced to an infinitely minute amount towards the centre. The lines themselves may be drawn or may consist of fine silk or wire stretched across, and fixed here and there with a spot of fish-glue or shellac solution.

The only other detail required is a rule accurately graduated to be affixed to the easel. A paper one can be permanently glued on or a wooden or ivory one may be let in flush with the front surface of the copy-board. A rule of exceptionally fine graduations is not at all essential to the method. A vertical line is drawn on the easel as near the centre as possible so that its image will fairly coincide with the centre line on the focussing screen. There should be no difficulty about this, and the easiest way is to stretch a piece of white cotton on the board and to focus it up. It is quite essential that the image of the cotton should coincide with the ruled line through all its length. The rule is to be fixed somewhere about the middle of the board, at right-angles to the line of the white thread, with zero right on the line and the graduations lying to the left, obviously upside down (fig. 4).

Fig. 4.

A little special care should be taken to follow out these details, for, once fixed, they need never be repeated, and it is a thing that if not done properly had far better not be done at all. If the procedure described has been followed the image of the rule will always be seen on the right-hand side of the ground-glass. It is the matter of an instant to slide the latter,

or the movable device, as the case may be, so that the left-hand line falls on zero of the rule image, and to observe the figure that the right-hand line cuts. Thus it becomes possible instantly to measure the image of the rule by the two-inch column on the ground-glass, and in focussing to get any desired length of rule image in that space. It is only required to remember how to find the amount of the image of the rule on the easel to be included in the two-inch space on the ground-glass. Even this need not be memorised, but can be typed out and fixed on the wall for instant reference. The formula is:—

Where D = Dimension of Original.
R = Result required.

$$2 \frac{D}{R} = \text{Length of rule to be copied to 2"}$$

Example: A plan drawn 1 in. to the foot is required 1 in.

to the yard. Three inches on the original is required to be 1 in. on the copy so $2 \times \frac{3}{1} = 6$. Six inches on the rule is to

go into the two-inch space on the ground-glass. This is an absurdly simple example, but so is the whole method once installed. If the original happens to be incorrect by reason of expansion due to damp or for any other reason this can be corrected in copying by adhering strictly to the above formula. When the camera has been adjusted and focussed in the manner described the original can be pinned up with the certainty that it will be sharp and to correct scale, without any further alteration to the camera. Some operators will be tempted to make a "final focussing" on the actual subject to be copied, but this will do nothing more than upset the accuracy of the scale, and is therefore to be deprecated as worse than useless.

D. CHARLES.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).

Bromide Wrinkles (Dec. 5).
Natural Poses of the Figure (Dec. 12).

THE REPRODUCTION OF NEGATIVES.

For a variety of reasons the necessity occasionally arises to reproduce negatives either in their original size or upon an enlarged or reduced scale. It may be that a negative of a celebrity or of a unique ceremony may be deemed of such value that it is desired to keep it as a "master" record and to print from the reproductions only, or a negative may be too thin or too dense to yield good prints, and it may be deemed too risky to submit it to the ordinary processes of intensification or reduction; or, again, it may be so stained or damaged that perfect copies cannot be printed in the ordinary way. Besides this, a separate negative of a portion only of the subject is needed, or enlarged or reduced sizes wanted for carbon or platinum printing. As we can control the contrast and density at two stages, the transparency and the negative from it, it is often possible to obtain results vastly superior to the original.

There are many ways of effecting our purpose, but I propose only to deal fully with that which most photographers will find most convenient, which is the making of as perfect as possible a transparency, and from that the negative. The character of

the original will largely affect the selection of the plates used for the purpose, as it may be necessary to modify the result considerably, and I therefore detail the kind of plates necessary to do this effectively, at the same time remarking that with average negatives any good brand of ordinary speed or slow plate may be used throughout.

For very thin negatives "process" plates will give the best results, as it is easy with these to obtain in the transparency considerably more contrast than there is in the original. Moreover, they are more amenable to intensification than ordinary plates, and there is very little risk of fogging.

Dense thick negatives, on the other hand, call for a more delicate film; special transparency plates coated with the emulsion used for lantern plates will be found to give the necessary delicacy of image. Failing these, an "ordinary" or "fine grain" plate will answer very well. Those who work carbon will find the special transparency tissue very suitable, as very thin delicate prints may be made upon a glass support, and if necessary these may be strengthened by staining or dyeing, or

even by intensification with pyro and silver solution. If the negative is to be made of a larger size than the transparency, the absence of grain in the carbon image renders it particularly suitable.

As a general rule I prefer to use a non-staining developer such as metol-hydroquinone, amidol, or Azol for the transparency. The same developers or pyro-soda may be used for the negative at the operator's discretion.

The exposure for the transparency may either be by contact or in the camera. For dense negatives the first is, as a rule, most satisfactory, while for thin ones the camera method is preferable. When making contact transparencies we must be careful to avoid parallax, which will destroy the sharpness in such areas as are not in actual contact. Modern negative glass is rarely quite flat, and as it is usually coated on the concave side it is possible to have the negative and sensitive plate touching at the corners only. Therefore it is necessary to have enough pressure to secure moderately good contact all over, and for this a frame with a plate-glass front and strong springs is necessary. With very fine diagram subjects I have even had to use a process frame with $\frac{3}{8}$ -in. plate-glass and screw pressure to avoid a spreading of the lines. In any case the printing frame should be kept quite still during the exposure, which should be made as far as convenient from an illuminant which is small in area. To give an example, I would give a distance of 5 ft. or 6 ft. from an unscreened inverted gas-burner, while with very thin negatives even a greater distance is recommended. The exposure should be long enough to yield an image which shows little if any clear glass. Lantern-slide quality is too hard, and will give harsh results. When using the camera the negative should be illuminated by a white cardboard reflector, and care must be taken to avoid shadows upon this, or the transparencies will be uneven in density. I frequently make both transparency and negative with an ordinary enlarging lantern, fixing up the plates on the easel, under the heads of small drawing-pins. As a rule, one or two thicknesses of ground glass should be interposed between the light and the condenser, except with very thin negatives, when a strong light and the full aperture of the lens will tend to give softness.

At this stage we may do much to even up our image either by locally shading the negative during contact printing or in the camera, or by shading the image in the way usual with bromide enlargements when the lantern is used. If a cracked or broken negative has to be dealt with, it should be printed by contact and kept in motion in a circular direction meanwhile. In this case we must risk parallax to avoid a greater evil. If such cracked negatives are very thin, they may be exposed through one or two thicknesses of white blotting-paper placed outside the frame, as this greatly reduces the effect of the edges of the crack.

Having obtained our transparency, we may proceed to inten-

sify or reduce it, either all over or locally, and when dry to retouch or work it up till it is as perfect as possible. On a transparency we have the power of strengthening shadows as we do lights in a negative, so that "knifing" is not absolutely necessary.

The exposure of the negative plate may usually be by contact unless the size has to be varied, when the camera or lantern may be used in the way already described.

If the transparency is still lacking in strength a process plate may be used and intensified in turn; by this treatment quite a vigorous negative may be obtained from a mere ghost of an original. In no case do I recommend the use of very rapid plates for reproduction work, as not only is the grain coarser, but there is not the latitude in exposure and amenability to variations in development found in a slower plate.

If reversed negatives are required, either the transparency or the negative must be made in the camera, the film side of the original being turned away from the lens. A simpler way by contact is to use a Portrait Film for one or the other exposure, putting the back of the film in contact with the film or the plate; as a matter of fact, with ordinary subjects either side of a film negative may be printed from without perceptible loss of sharpness.

The simplest way to reproduce a negative is to copy a print, and this is extensively done in many establishments. There is, however, usually a noticeable loss of quality when bromide or platinum prints are used, and I much prefer to work from a rather lightly printed P.O.P. copy, which is put under pressure in a plate-glass printing frame and copied *without toning or fixing*. With care the exposure may be made by daylight if all preparations are made before uncovering the print, but a better plan is to expose by ordinary metallic-filament lamps or even incandescent gas light, which have practically no effect on the sensitive paper.

Several processes have been published by which a negative can be produced direct from another negative, but they can hardly be said to be adapted for everyday use. If a plate be greatly over-exposed, a reversed image is produced, but usually of a foggy character. Sensitising an ordinary dry plate in bichromate, and printing until the image is visible at the back and then developing and fixing, will produce a negative from a negative, the exposed parts having become insoluble and impermeable to the developer which acts upon the remainder of the film.

The "dusting on" or powder process will give excellent results by a single operation, but the manipulations required are too delicate for the average photographer. All the foregoing "direct" processes yield reversed negatives, which are only needed for single transfer carbon and certain photo-mechanical processes.

PRACTICUS.

A SMALL FINISHING PLANT.

[The following article is quoted from our San Franciscan contemporary, "Camera Craft," for its very full description of the outfit used for "photo-finishing," as the development and printing of amateurs' film exposures is called in the United States.—Eds. "B. J."]

WORKING in a few finishing shops, visiting a number of large plants in the East and Middle West, including the Eastman model plant and running a small shop of my own, may, I trust, justify my presumption in offering a few suggestions on the developing and printing of amateurs' film negatives. The methods advocated may, in some cases, vary from the makers' instructions, but such departures have been found either to save money in original cost or economise time getting out the work.

When the work comes in, the first thing to do is to get it

booked. The simplest and most accurate method of handling up to three hundred rolls a day is to enter the orders in a cheap day book. A serial number is given each order, and the entry is made like this:—

718

Mrs. John Jones, Jonesville, Wis.

1—116—6

1 ea. (meaning one print of each good).

In the case of an agency or other large customer the name only can be stamped in with a rubber stamp. The next line of

The entry shows the number of rolls and size, while the last shows just what work is to be done. Start the numbering with 1 each week, in order to keep it low. At the same time that the order is booked the number is placed on the roll or rolls.

When a tank full of films have accumulated, develop them. Placing the films on a small shelf, with a ruby light in front of you, the numbers can be seen on the roll. Repeat them on the film, using a blue "glass-marking" pencil. Ordinary lead will stick, but this kind of pencil is better, and rarely rubs off. The pencil has the advantage over scratching or punching methods in that the number can be easily erased when it accidentally overlaps on the picture, as it sometimes does.

After the films are marked and stripped, they are doubled back, face out, and the ends fastened with a Kodak, Jr., clip. In the case of small films, No. 2 Brownies, etc., two films can be placed back to back, with a clip on each end. The film-holder is hung up by the hooked handle before work is begun, and as each film is stripped it is hung upon one of the rods in the hanger. Several can be placed on each rod. Film packs can be handled best by the use of Premo back-hangers; but though these can be developed along with the roll films, it is best to handle them separately, as they require about 50 per cent. longer development. Plates can be handled easily by using a plate tank-rack on the end of a strong cord that permits it being lowered to the bottom of the tank out of the way of the roll films.

The best developing equipment that I have ever seen, using tanks smaller than the 48-gallon stone ones recommended by the Eastman Company, is one employing sewer-pipe tanks. The vitrified clay sewer-pipes are absolutely acid, alkali, and water-proof. And they are cheap, compared with wood or copper. Obtain four sections of this pipe, each 4 ft. long and of a diameter suited to your needs. I used 10-in. pipe for a while, handling about thirty rolls at a time. Build a platform of 2-in. plank, about 6 ins. from the floor, and make it wide enough to hold the pipe, and place the sections, flange-end up, on this platform.

If drain-pipes are wanted, the next thing to do is to arrange them in place. These, with the necessary elbows, valves, and other fittings, should be so placed that the ends of the pipes extend through the board into the bottom of each tile section with the valve-handles between the platform and floor, where they can be reached easily. Allow the upper end of these drain-pipes to project about 2 ins. above the plank, inside the tiles. When they are arranged to your satisfaction, pour about 2 ins. of concrete, half sand and half cement, into the bottom of each tile and allow to harden. Some rags stuffed into the ends of the drain-pipes will protect them from concrete that might flow in. When the concrete has set, pour enough real hot paraffin into the bottom of each tank to coat and protect the concrete thoroughly. If you do it quickly you can drain the surplus out through the drain-pipe, and thus give a coating to the interior—i.e., that part above the valve that will be exposed to the chemicals.

If your climate demands it, a water-jacket for cooling the contents can be built around the developing tank. A cylinder made of galvanised iron—one slightly larger than the sewer-pipe—can be set around the tank. This should first be coated with Probus paint, except for an inch or so at the bottom, inside; then placed in position, and 2 ins. or 3 ins. of concrete poured in. The water-jacket is then on the developing tank for life.

Have the tinner make two or three film hangers, shown beneath printer in the drawing, the size being determined by the inside diameter of your tanks. Make them from 10-gauge iron wire, and have at least an inch between the spoke-rods at the edge of the 4-in. metal centre. Have the ends of each rod turned up about one-half inch, in order to prevent the films slipping off. The upright hook in the centre, for hang-

ing up while filling, should be at least 6 ins. long. When the holder is completed, give it one or two coats of Probus, and keep the metal coated at all times in order to prevent staining of the films. A circular tin cover with a tight-fitting flange will protect the developer from the air, and greatly reduce oxidation. This should also be coated with Probus paint.

I have had very satisfactory results, using a small tank, with a twenty-minute developer, made as follows:—

Water	128	ozs.
Kathol	1	oz.
Hydroquinone	1	„
Sodium carbonate	5	ozs.
Sodium sulphite	5	„
Potassium metabisulphite	80	grs.
Potassium bromide	25	„
Sodium hydrate	65	„

Add water to make 640 ozs. This developer gives fine contrast suitable for amateur work; is non-staining, oxidises very slowly, and will develop more films than any I have used.

While the films are being developed the envelopes can be made out, using the order book and making a check mark opposite each entry to show that this has been done. The envelopes should bear the film order number and customer's name.

The second tank is used for rinsing tank; and, while the washing tank can be used for this purpose, it will double the capacity of your tank system to use a fourth tank also for rinsing. The hypo is mixed according to the standard acid-hypo formula, though, in the cooler seasons, very little hardener is necessary. Theoretically, the amount of silver which could be recovered from a tank full of exhausted hypo would be worth some trouble: the fact that the tanks must be used every day, and the silver has to be precipitated as a sulphide, makes me doubt the advisability of bothering with it.

Strong spring clothespins, stretched on a wire or light rope make a convenient arrangement for drying. The wet and slippery end of the film may slide out, and it is therefore advisable to drive a couple of small tacks through the end of each clothespin, thus forming a puncturing point that will hold the heaviest film. The average finisher thinks that a drying cabinet is almost a necessity. It isn't. If one will fix his drying line, either at or near the ceiling or so arranged that it can be raised there, the warm air at the top of an ordinary store or room will usually dry films in an hour or two.

After the films are dry, check them against the original entry. On the end of the film, near the number, write the instructions with a pencil; 1 ea., 2 ea. D. O. (develop only), or whatever they may be. At the same time sort the films according to size, thus saving a good deal of time in printing. The films are taken to the printing room without cutting up.

Two printers rank first for amateur finishing work, in my estimation. One of these is the Pa-Ko printer, which though not inexpensive comes closer to being an ideal printer than anything else on the market. Plenty of lubricating oil, and some rubber attached to such points of shock as the lever operating the pressure board, will help a lot. The other is a home-made printer that can be constructed for less than five dollars. The drawings herewith show the details. No measurements are given, as the individual worker will vary the size to suit himself. The top, which should slope slightly towards the operator, has a 7 x 5 glass fitted into the top, so as to leave a smooth surface. A nitrogen bulb in a circular reflector furnishes the printing light; while a small ruby bulb gives the illumination necessary for adjusting the mask and negative, as well as for judging the density and contrast. A strip of wood, $\frac{1}{2}$ in. thick and 2 ins. wide, hinged to the right hand front leg near the bottom, controls the lights by a sideward movement of the knee. In place of the usual hinged pressure board, use a block of inch wood, about 6 x 4,

with a sheet of felt over the under side. In the centre of this cut a hole to accommodate an ordinary self-inking rubber stamp. The metal legs should be cut off so that they cannot come in contact with the paper and negative. This stamp is fitted into the centre opening and screwed to the block so that the numbers will just come in contact with the paper. The felt covering on the bottom of the block is, of course, cut away where the stamp operates.

The masks may be home-made, but I have found the Eastman transparent masks, with trimming guides, easier to adjust, and the guides made it possible for a girl to trim prints faster and more accurately. In any case, a mask for each size used is fastened to a separate piece of 7 x 5 glass, a wide rubber band around the mask and glass holding the uncut film in place.

Thus equipped, the paper can be adjusted very quickly and the numbering pressure block held down upon it, a movement of the knee switches on the printing light at the same time. The big advantage of this type of printer lies in there being, practically, no weight to move. The numbering stamp, being built into the pressure pad, numbers the print while the exposure is being made. A quick-drying rubber-stamp ink should be used, and used sparingly, to avoid any blurring of the number or soiling of the next print. There is little to get out of order with this printer. The operator is not tired with a heavy pressure board that must be raised and lowered, and the number cannot be left off a print through accident.

A small strip of yellow celluloid will enable you to mask off the fogged or short end of a negative. The same number that is on the film can be used on the print, but it is much easier to begin every morning with a new print number, the first order printed each day bearing the number 1, the second 2, and so on, this saving time in setting the stamp. The number should, in all cases, be stamped on the end of the film. If there is no paper remaining there, a small sticker can be attached to take this stamped order number. An initial or key number will show, where there is more than one printer, which one made the print, and such a number will also simplify the sorting.

In my own work I use both Azo and Cyko paper. The former has the advantage in price, and is used by many finishers. Of the latter, I use Studio Surface, in the three regular grades, and some "Professional" for very blocky negatives. Two sizes are enough, and their use simplifies matters. Use 6 x 4, full size, for postcard stuff, and cut it in two for $3\frac{1}{4} \times 2\frac{1}{2}$. Use 7 x 5, cut in two, for $4\frac{1}{4} \times 3\frac{1}{4}$ and $4\frac{1}{4} \times 2\frac{1}{2}$. Cut in quarters, it makes a good size for "vest pockets" and smaller. In using Cyko it really saves time and trouble to buy the 500-sheet boxes of amateur finishing size paper. By the use of paper guides on the printing masks the prints can be made with even margins on two sides and thus decrease the trimming, but personally I prefer to turn out prints trimmed on all four sides. The edges of any print pick up dirt, show abrasion, and the corners show some damage in the washer.

Iron baking-trays, painted with Probus, make good trays for the acetic acid short stop and acid fixing-bath. Be sure and keep both of these fresh and strong. Nothing is more depressing than having a lot of stained prints to make over, particularly during the rush season. A big wooden spoon makes a good paddle for the short stop and hypo. An electric light, white, fitted in the bottom of a 1-lb. soda can and hung a foot or so above the hypo tray, will enable you to see the real tone, depth, and quality of the prints. The makers' formulæ should be used for all paper development.

For washing small-sized prints there is nothing that will beat a rotary washer, and a good one can be made as follows: Take a piece of 1-in. hardwood and cut two circles, 10 ins. in diameter, to be used for ends. With these make a cylinder of $\frac{1}{4}$ -in. mesh galvanised screening, 20 ins. long, with a hinged door, made out of the same material, in

the side. Place a bolt in the centre of each end-piece for an axle, and supply one of these end-pieces with small galvanised iron paddles, arranged as on a water-wheel or water-motor. This circular cage is then mounted in a tank so that its top will just come above the water level. The water inlet, directed against the paddle-wheel end, causes the cage to revolve and keep the prints separated and in motion. The overflow outlet is at the top, and the drain-pipe in the bottom can be used to prevent hypo-laden water from settling there, as well as for drawing off the water for easy removal of the prints. The diagram should make all clear. Notice that the head of the bolts used as axles are sunk into the wooden ends so that they will not catch and tear the prints. The two bearings on which these axles revolve are shown in the drawing, the form of the hole in the one at the left permitting of the revolving part being removed for cleaning if necessary. One of the galvanised paddles or vanes is also shown below. Fifteen to thirty minutes in such a washer as this eliminates all hypo. from the prints, or you might buy one of the excellent Rex washers, made by the Northern Photo. Supply Company, of Minneapolis.

Formerly I dried my prints on a stretcher; but, finding that

Printing-box, washer, etc., used in the making of prints from amateurs' film negatives.

they curled too much and dried too slowly, I bought a blotting-paper and corrugated board drying roll, such as the Eastman Company supply for their Majestic drier, costing about three dollars. Rolled up in one of these, the prints dry about as fast without heat as they do on a stretcher. Set over a hot-air register or near a radiator they dry as quickly as in a regular drier.

If you lack these sources of hot air, have a tapered, galvanised-iron cylinder made, with one end large enough to receive the end of the blotting-paper roll, the other end small enough to just take a 6-in. fan blade. Fasten the galvanised-iron cylinder in an upright position with a cheap electric fan at the small or lower end, with a gas-burner or small oil-stove near and slightly below. Roll up the prints in the roll, stuff the inside of the roll with an old piece of cloth, and drop in the funnel. With such a drier, about fifteen or twenty minutes will dry your prints; and no matter whether heat is used or not, they will come out flat and with a slight backward curl.

The sorting of the prints is done by first laying out the films on top of their respective envelopes, the original glass-pencil number on each film corresponding with its envelope number. The number stamped on the end of the film, in the printing room, corresponds with the number on the prints. If sorted first and trimmed later, the order can be checked and inspected for imperfect prints at the same time that it is trimmed.

A 10-in. trimming board, with a slot in the bench just beneath the edge for carrying off the paper trimmings, is used. If the trimmer is set on a special built-up table and a small 15-watt lamp arranged under the cutting edge in such a way that the light shines past the edge and through the print, it will be found that the correct margin can be judged more quickly

and the prints trimmed faster. The light, however, must not shine into one's eyes.

As the envelopes are checked, and the amounts due marked on them, the order book is again brought into play, and each order checked against it once more. A large check-mark is made through the order, and the amount due is marked at one side.

A few miscellaneous suggestions and I will close. For general lighting of the printing room, use either an Ingento indirect lighting fixture or else make one like it by taking a tin wash-basin, wire an orange bulb into it, hang it a few inches from the ceiling, and paint a white enamelled circle right above. You will be pleased with the result. In fitting up a printing room or a tank room, do not paint it black unless you want to see how much dirt you can collect in it. Paint the walls white or some very light colour. Be sure that the room is light-tight and that your ruby and orange lights are safe. The light-coloured walls will reflect much of the light, and the corners and floor will be well enough lighted to enable you to see things that you may drop; in addition to being safe from fog the light-coloured paint will practically force you to keep the place clean. A clean work-room, seen by a customer, at once stamps you as an unusual finisher.

Build your developing tanks large enough. If you choose your developer with a view to its keeping qualities you will be able to use it until exhausted; and, when you do this, there is nothing to be gained by having a smaller tank. In addition, the larger tanks will enable you to get your films developed during a rush season, without working all night.

Have at least one more printing machine than you think you need. A finishing business can increase suddenly at times, and the printing room is generally the weakest link in such a shop.

Keep the work moving through at all times. Too much book-keeping can do more harm than good. If you have all the films that came in the morning or the night before developed, printed, and in the envelopes by five o'clock, there is no danger of getting them mixed up with the next day's work.

A small finishing business, built upon a foundation of good quality, prompt service, and reasonable price, has nothing to fear from the mail-order finisher or the larger finishing plants. A good black tone—one that is not muddy, olive, or blue—accurate white margins, twenty-four hour service (or less), and satisfaction to your customers—these are all that any finishing shop needs for success.

G. W. GREENE.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Bromide Toning Processes.

Most photographers use bromide paper these days, and quite a large proportion of the prints made on this material are toned by one process or another. Now sometimes the toning process used is absolutely the best possible for the conditions under which it is to be used and the results desired, but quite often this is not so. Professionals are very apt to get into a groove and stick there, and whatever toning process was used first is usually carried on with, without much consideration as to whether it is the best for the purpose or not. It is the purpose of this article to give brief notes on the principal processes, and indicate for what class of work each is best suited.

We will first take toning processes for the production of sepia tones. There are three main classes: (A) Hypo-alum, (B) bleach-and-sulphide toners in several forms, and (C) liver of sulphur, a little-known, but most efficient, toner.

Hypo-alum is the best toner of all for quantity production. It is, on the whole, better suited for large batches of cheap or medium class work than for really high-class prints, although with due care beautiful tones may be obtained. Taking it on the whole the

tones given by this method are rather inclined to purple. It is almost always necessary to use a hardening bath for the prints to be treated. The toner must be used hot if it is to work in a reasonable time. It appears to reduce prints slightly, especially when newly mixed. It is apt to deposit a scum on the prints, which should be swabbed with cotton-wool, and any fault in the paper base is likely to cause blisters on the prints. These are all its faults, and many of these will not be found of any great disadvantage in practical work. The virtues of hypo-alum are many and great, chief among them being regularity of tone, ease and speed with which large batches may be handled, and economy of cost. It is the cheapest of the sepia toners, and is the one most frequently used by trade printing houses. It should be mentioned that this is the one photographic solution which improves with use.

Our next group—bleach-and-sulphide—is rather complicated by the fact that many different formulae have been published for obtaining the same result. There is not a lot to choose between them as a rule. They fall under two main heads, bleach of potass ferricyanide and potass bromide, and bleach of permanganate, as brought forward by Mr. Greenall. I think the former is the better for general use, as it is more simple to use, but I believe that Mr. Greenall's method scores on the ground of cheapness. The usual formula gives potassium bromide in the bleacher, but it is an advantage both in cost and in the colour of the resultant prints to use ammonium bromide in its place. Taking bleach-and-sulphide methods on the whole, the advantages are: Very fine tones, ease in working small or medium size batches, cleanness of results, and the surety that the chemical action is complete, of which latter more later. The disadvantages are the liability of any impurity in the water to cause spots and markings, and the fact that small differences in the time of development of the prints make a big difference to the resultant colour.

These are, to my mind, the best processes to use when a fair number of first quality prints are wanted. It should be noted that when these processes are contemplated amidol is the ideal developer, not only for the fine colour it gives, but because it does not soften the emulsion of the prints as a developer containing an alkali must do, which is a great score in a process so liable to give blisters as sulphide toning.

There are many variations of these methods. One of the best is to place the print in the sulphide for a few moments before bleaching. They must be washed thoroughly before being proceeded with in the usual way; this gives very rich tones, but it is not easy to get big batches all the same colour by this method. Or another good dodge is to bleach in the usual way, and then darken in pyro developer. The colour so obtained is rather a pleasing olive black. The bleached print may be partially darkened in any non-staining developer, and finished with sulphide. Quite a good range of warm blacks may be got in this way, but it is difficult to repeat them. Schlippe's salts may be used in place of sulphide for darkening, but it requires a really first-class original print. Then the tones are good and varied, but unfortunately variable.

The method suggested by Mr. H. W. Bennett, in which bichloride of mercury is used as the bleach, the darkening being done in sulphide, is a most interesting and useful one, but it can hardly be recommended as a commercial process because of the very deadly nature of the bichloride. It is a pity, because for warm blacks and deep browns the method is unbeatable.

Any sulphide-toned print may be further toned with gold—the usual P.O.P. formula; the results range from warm brown to red chalk. They are most effective, and may be considered permanent.

Our last sepia process is, to my mind, the most beautiful of all, and it is certainly the least known. It is the liver-of-sulphur method. Its advantages are in the beautiful tones it gives, in the fact that it is a one-solution process, so that the change of colour may be watched and stopped at the right time. It gives very fine tones on gaslight papers, which with ordinary methods tend to give yellow results. The disadvantage of liver of sulphur is the fact that it is not suited for large quantities. But I think it the ideal process for just a small number of really first-class results.

Now a word as to a most important matter—permanence. Leaving out of consideration the decomposition of the gelatine in which the image is formed, the only change likely to take place in the untoned print, providing it was well fixed and thoroughly washed,

is the conversion of the silver image into one of silver sulphide, by exposure to an impure atmosphere. Now this is absolutely the same thing as sulphide toning, only the process may take years to show and never be completed. It is, therefore, obvious that a sulphide-toned print stands a better chance of remaining unchanged than an untuned one, and, further, that the more complete the change the better the chance of absolute permanence. It is here that the bleach processes score, because it is essential that both the bleaching and the darkening shall be thorough if a passable result is to be obtained. In the case of a single solution toner the action may be incomplete, and it may, therefore, continue under bad conditions. It will not cause fading, or even any very marked change in colour, but it may be quite enough to make well matched spotting show up very badly.

On the whole, however, one may say that, so far as the image itself is concerned, a sulphide-toned print is unbeatable for permanence among silver images.

These are the processes most likely to find favour, but there are several other methods of toning which may be useful. Foremost among these is copper toning. This is a cheap and convenient toner for colours, from warm black to red chalk. It is used in one solution, so that the extent of toning may be observed and stopped at the right moment. The results of copper toning were at one time thought to be impermanent, but this must have been to a large extent due to careless methods of work. The prints should be at least as permanent as untuned prints.

The ordinary gold-toning bath, as used for P.O.P., may be used on untuned bromide prints, and will give a striking and not unpleasant blue-black effect, which may be found useful for special effects, especially strong lightings. The results are considered fairly permanent.

Uranium toning was at one time a very popular process, and it is still largely used in cheap studios for red chalk tones. It is, unfortunately, a most impermanent method, and its use is not to be recommended except for the cheapest work.

Green tones are best obtained by the use of Mr. H. E. Smith's formulæ, as given in the "B.J. Almanac." This is not quite so simple to make up or to use as some formulæ, but the results are fairly permanent, which is more than can be claimed for most green tones. In addition to this, the colours are quite pleasing.

The blue-toner given in the "Almanac" is also about the best for general use, the colours being really good. But, to my mind, when only an occasional print is to be treated, it is far better to buy the blue and green toners in tablet form. In this way the purchase of a number of uncommon and, for other purposes, useless chemicals is avoided, and the solutions may be prepared fresh with the least possible trouble. Of course, if a regular line is to be made of it, it is cheaper to mix your own.

In conclusion, may I suggest that to any photographer of an experimental turn of mind toners offer a wide and interesting field? They may be very profitable, too, for a unique tone is a wonderful "draw" for a studio. Experiments might be made not only in the way of combining known toners, but in the use of new reagents.—ARTHUR G. WILLIS.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 1 to 6.

FILMS.—No. 29,861. Photographic films. W. H. Edridge.

FILM CAMERA AND SPOOL.—No. 30,454. Focussing film camera and spool of film. F. G. Cook.

PRINTING MACHINES.—No. 30,331. Photographic printing machines. B. J. Hall.

FILM WASHING AND DRYING.—No. 30,363. Washing and drying photographic films, etc. S. R. Pearse.

CINEMATOGRAPHY.—No. 30,470. Cinematograph projectors. Sir O. Stoll.

CINEMATOGRAPHY.—No. 30,471. Cinematograph cameras. Sir O. Stoll.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINT-DRYING MACHINES.—No. 134,771 (May 9, 1919). The invention relates to means for drying photographic prints and to that class of machine, for example, described in Patent No. 121,936. In this class of machine a drying drum is heated by means of hot gases, and is rotated by means of a worm wheel actuated by a

Fig. 1.

worm which is driven by a suitable motor, an endless band or apron being provided in conjunction with the drum or cylinder and mounted on rollers, the tensioning roller being adjustable so that the tension of the apron can be regulated and a squeegee

Fig. 2.

being provided to remove the surplus water from the drum or cylinder.

The object of the present invention is to provide a compact machine of that class which can be easily assembled and dismantled.

The drying drum is carried at each end by means of a spider frame placed within the supporting frame and bolted to the end face of the drum and rotatably mounted upon a sleeve secured to a vertical upright forming a portion of the supporting frame.

The worm wheel is secured to the spider at one end of the drum by means of bolts near the teeth of the worm wheel, and the worm gearing is carried by a spindle mounted in bearings within the frame.

In conjunction with the drum or cylinder there is provided the usual endless band or apron mounted upon rollers arranged in the usual way so that the points are passed around the drum between its surface and that of the band, the band being brought to the requisite tension by means of counter-weighted levers, which carry by means of links the tensioning roller which moves in slides or guides in the machine frame. At its upper part the drum is furnished with a squeegee roller, the function of which is to remove from the prints to be dried the surplus water, which flows over the surface of the drum on to a shelf supported in the frame and furnished with a groove for the escape of the water.

The guide-rollers for the endless band or apron are supported in bearings or upon pivot pins in the sides of the machine frame, these pivot pins extending into axial holes in the ends of the rollers and being screw-threaded so as to engage screw-threaded holes in the frame in which they are secured or locked in position by means of nuts. The worm shaft is carried in a pair of bearings which are easily detachable from the frame, each being advantageously secured to the frame by means of a lubricating cup which is furnished with a screw-threaded socket engaging a screw-threaded stem or shank on the bearing, which stem extends through a hole in the machine frame, and a lubricating passage extending through the bearing stem and connecting the bearing with the lubricating cup.

The drum and band or apron are preferably driven from an electric motor which is conveniently fitted upon the top of the

Fig. 3.

Fig. 4.

machine frame and drives the worm shaft through the medium of any suitable speed-reducing gear.

In the drawings *a* indicates the base of the supporting frame of the machine and *b* the two upright sides. *c* indicates the drum which is heated, and is carried by the end spiders *d*, each of which is rotatably mounted upon a flanged bearing sleeve *e* secured to the sides *b* of the frame by means of the bolts *f*.

c' are ventilating holes provided in the ends of the drum, and *g* is a pipe which serves for the introduction of gas or electric current into the interior of the drum. In the interior of the cylinder *e* the tube *g* is furnished with a support carrying at its upper end a gas burner or electric heating element.

A indicates the endless apron or band which is passed around the guide rollers *i* rotatably mounted in bearings carried by the sides *b* of the frame, and in such a manner that the apron envelops the outer periphery of the drum *c* for the greater part of its extent in the usual manner, as shown in fig. 1. The roller *j*, which also serves as one of the guide-rollers, is used for the purpose of imparting the requisite tension to the apron, the roller, for this purpose, being carried by links *k* so that it can move in lateral slots *k'* in the sides *b* of the frame, the links themselves being pivoted to the short arm of counter-weighted levers *l*, which are pivoted at *l'* to the machine frame *b*.

A suitable form of bearing for the guide and tension rollers is shown in detail in figs. 3 and 4, and comprises the screw-threaded pivot pin *m*, which is screwed into the machine frame *b* and secured or locked by means of the nut *m'* and enters an axial hole *m^2* in a metal end piece *m'* provided upon the roller. This method of

mounting is not only simple in construction, but also permits of the rollers being assembled and dismantled quickly and with facility. The drum *c* is driven by the following mechanism, that is to say, the worm wheel *n*, which is secured to the spider *d* at one end of the cylinder by means of bolts near the teeth of the worm wheel, and is in mesh with the worm *o* keyed upon the spindle *p*, which is mounted in bearings *q* secured to the machine-sides *b*, and is driven by means of the belt and pulley gear *g*, *q* from the counter-shaft *r* itself driven from an electro-motor indicated diagrammatically at *s* in fig. 2, and mounted upon the upper part of the machine frame.—Sydney Harold Morse, Finsbury Pavement House, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, DECEMBER 20.

Dennistoun Amateur Photographic Association. 12th Scottish National Salon, People's Palace.
Partick Camera Club. 12th Scottish National Salon opens in People's Palace.

MONDAY, DECEMBER 22.

Bradford Photographic Society. "Tips and Dodges." B. Riley. "Copying." W. H. Hammond.
City of London and Cripplegate Photographic Society. Members' Print Competition.

TUESDAY, DECEMBER 23.

Hackney Photographic Society. Chat Round the Fire.
Bournemouth Camera Club. "One Man Show." F. J. Mortimer's Prints.

WEDNESDAY, DECEMBER 24.

Croydon Camera Club. Conversational Meeting.
Dennistoun Amateur Photographic Association. "Portraiture Before the Days of the Camera." J. Huck.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A SPECIAL general meeting of the Professional Photographers' Association was held at 35, Russell Square, London (the house of the Royal Photographic Society), on Friday, December 12, 1919, for the purpose of altering the rules.

In the unavoidable absence of the President of the Association, Mr. R. N. Speaight took the chair. The Honorary Secretary having read the notice convening the meeting, the Chairman explained that the object of the proposed alteration of the rule was to give the Council power to employ either a paid or an honorary secretary or both, as they may think fit. According to the existing rules they were bound to appoint an honorary secretary. The Council required greater freedom of action in view of the increasing membership, activity, and importance of the Association. He therefore moved, on behalf of the Council, that Rule 10 should be amended and should read as follows:—

"10. Officers.—The honorary officers of the Association, constituting the Council, shall be a president, the past-president, a treasurer, and twenty-four ordinary members of Council, of whom twelve shall be London and twelve country members. They shall have power to appoint a secretary and/or an assistant secretary, who may be paid. At meetings of the Council five shall form a quorum."

A brief discussion followed, and subsequently the resolution was carried unanimously.

A vote of thanks to the chairman closed the proceedings.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 16, Dr. G. H. Rodman in the chair.

Mr. N. E. Luboshez was to have given a demonstration of fancy lighting in portraiture, and had temporarily installed a number of electric lamps for the purpose. Owing, it must be supposed, to some overloading of the electric system, some fuses gave out, and it was unfortunately not possible to replace them in time for the demonstration to be given. Yet those who know Mr. Luboshez will not doubt that under this disability he was nevertheless able to deliver a fluent and interesting discourse on the subject which it had been his

intention to demonstrate. The demonstration itself will be given at one of the meetings in February next.

On the proposition of the chairman, the thanks of the audience were cordially expressed to Mr. Luboshez.

Commercial & Legal Intelligence.

NEW COMPANIES.

SOUTHGATE BROS., LTD.—This private company was registered on December 4 with a capital of £5,000 in £1 shares. Objects: To carry on the business of photographers, etc. Agreement with W. E. and L. Southgate. First directors are W. E. Southgate, 33, Queen Street, Maidenhead, and L. Southgate, 33, Queen Street, Maidenhead, both photographers. Registered office: 33, Queen Street, Maidenhead.

GARNETT PICKLES PREPARATIONS CO., LTD.—This private company was registered on December 9, with a capital of £3,000 in £1 shares (1,500 8 per cent. cumulative preference). Objects: Manufacturers of and dealers in photographic apparatus and materials, etc. The subscribers (each with one share) are:—T. H. Bailey, 25, Windermere Avenue, N.3, chemist, and R. Garnett Pickles, 7, King's Parade, N.3, chemist. The first directors are R. Garnett Pickles (managing director), T. H. Bailey (chairman), H. A. F. King, and L. A. Moores. Registered office: Cromwell House, High Holborn, W.C.1.

WALTON ADAMS AND SON, LTD.—This private company was registered on December 6 with a capital of £3,000 in £1 shares (1,000 6½ per cent. preference). Objects: To take over the business carried on at 29, Blagrove Street, Reading, by A. W. Adams as "Walton Adams and Son," and to carry on the business of photographers, photographic artists, picture dealers, etc. The subscribers (each with one share) are P. P. Crowe, 149, Ongar Road, Brentwood, photographer, and T. W. Alderman, 19, Warwick Road, Upper Clapton, E.5. The first directors are P. P. Crowe and T. W. Alderman (both permanent). Secretary, Winifred Crowe. Registered office, 29, Blagrove Street, Reading.

News and Notes.

M. MISONNE'S PHOTOGRAPHS.—An exhibition of the charming landscape work of M. Misonne, who may appropriately be called the Corot of photography, will open at the Hampshire House Photographic Society, Hog Lane, Hammersmith, on January 1 next.

LECTURES ON APPLIED OPTICS.—Among the lectures to be delivered at the Royal Institution, Albemarle Street, London, W., after Christmas are two on "Recent Progress in Applied Optics," by Dr. A. E. Conrady, Professor of Optical Design, Imperial College of Science, London. The lectures will be delivered on February 5 and 12 at three o'clock.

KEROtype MATERIALS.—In our brief notice last week of the series of demonstrations of the Kerotype process at Messrs. Marions, it should have been stated that Messrs. Marions are sole wholesale distributors of the Kerotype papers, and that all communications relating to the buying and use of the papers should be addressed to them at 3, Soho Square, London, W.1.

TWO "B.J." SPECIALS.—Two of the little handbooks issued from the "B.J." office have just been published, each in a fourth edition. These are the "Portrait Studio," by "Practicus," price 1s. net (postage 2d.) and "Sketch Portraiture," by J. Spencer Adamson, price 9d. net (postage 1d.). Both these little manuals treat of their subject in an eminently practical way, and the continuous demand for them is no doubt the best tribute to their usefulness to the photographer which could be made.

J. F. SHEW AND CO.—In reference to our note of last week, Mr. W. J. Ramsey writes to us from 62, Wellesley Road, Harrow, asking us to point out that Mr. Garrad was never manager of Messrs.

Shew's business, of which Mr. Ramsey was sole proprietor, nor had he any connection with the business whilst under the title of J. F. Shew and Co. Mr. Ramsey eventually sold the business to Messrs. Garrad and Dale, who were carrying on the business of Staley and Co., and it was on the completion of the sale that the businesses were combined under the title of Staley, Shew and Co.

LECTURING WITH THE LANTERN.—A somewhat revised text of an address on lantern lecturing delivered by Mr. Grenville A. J. Cole, F.R.S., to teachers and lecturers at the Royal College of Science for Ireland has been issued in pamphlet form by Mr. T. H. Mason, optician and lantern-slide maker, 5 and 6, Dame Street, Dublin. Mr. Cole deals with a subject of great interest to photographers and to photographic societies in so human and humorous a way that with his permission we hope to print his paper in a forthcoming issue of the "B.J." In the meantime there must be many who would like to possess the pamphlet in separate form, as they may do by application to Mr. Mason.

A NEW SANDS-HUNTER LIST.—A supplementary list of second-hand apparatus has just been issued by Messrs. Sands, Hunter and Co., Ltd., 37, Bedford Street, Strand, London, W.C.2. It is a well-printed catalogue of eighty pages, every item of apparatus in which is identified by the firm's series number, so that the intending purchaser is able to indicate the goods which he wants with the least possible outlay of trouble. Moreover, the clear classification of the goods, both cameras and lenses, under their various headings, makes it the easiest matter for the intending buyer to satisfy himself as to whether he can get what he is seeking. In the case of lenses a particularly clear tabular arrangement has been newly adopted, the type-setting of which affords a rapid glance over the particulars of each lens offered—viz., focal length, aperture, plate covered, and price. Inasmuch as the trade in photographic apparatus has of late gravitated largely towards the supply of second-hand goods, Messrs. Sands, Hunter's catalogue is a piece of trade literature of special importance, in fact one which no photographer, professional or amateur, can afford to overlook whenever he has a purchase to make.

Correspondence.

. *Correspondents should never write on both sides of the paper.*

LENS-SEPARATION IN STEREOSCOPIC PHOTOGRAPHY OF SMALL OBJECTS ON THE SAME OR AN ENLARGED SCALE.

To the Editors.

Gentlemen,—Mr. Chas. E. Benham's formula for finding the separation of the lenses seem extremely good, but appears to call for a few comments.

If the requirement is to render the object as it appears to the naked eyes at their near point (12 ins.), then it will not do to take the lenses closer than 12 ins. to the object, because impossible visual perspective will be introduced.

If natural perspective is required then I would suggest that 6-in. lenses be used at 12 ins. distance, thus getting natural size. Then if that be not large enough when viewed in a magnifying stereoscope, enlargements from the negatives should be made and mounted up as stereographs.

I am glad to see Mr. Benham gives the optical axes converging, because most writers—and camera makers too—seem to presume that they must always be parallel.

And this is why the formula "leads us astray" at greater distances, because as the object recedes so the convergence of the optical axes should decrease until at a few yards they become practically parallel.

To make the formula a little more exact I would suggest that the

2½ ins. be reduced to 2¼ ins. I have measured the interpupillary distances of hundreds of patients, and I find that the average when the eyes are fixing infinity is 2½ ins., and while fixing a point at 13 ins. the average comes out at 2¼ ins. This seems to show that most stereoscopic photographs are taken with the lenses set a little bit further apart than the average human eyes. The difference though, of course, is trifling.—Yours faithfully,

ARTHUR G. WILLIAMSON.

A WARNING AS TO THE USE OF FORMALINE IN TROPICAL DEVELOPMENT.

To the Editors.

Gentlemen,—I have noticed during the past year or two a tendency to advise the use of formaline in fixing baths for use in the tropics.

My experience in tropical photography covers over thirty-five years, and during the major portion of that time I had been travelling in the bush towns, where there is no ice available, and where the only means of obtaining cool water is by means of the well-known canvas "water-bag."

About twenty years ago formaline was being listed as a regular thing in our photo-chemical lists, and I tried it for the purpose of hardening the film so that I could develop without so many of the usual cooling precautions. It acted all right both as a preliminary bath and as an admixture in the fixing bath, but I gave up the use very soon on account of the injury to my eyes.

I think, so far, my experience was about the same as that of the present-day experimenters in the use of formaline, but note the sequel. Four or five years later, when looking up old negatives for re-orders, I noticed occasional ones which were cracked all over like a fine mosaic, and on rubbing them with the finger the cracked film could be reduced to a dry powder. I eventually found that these were the formaline-treated negatives; the tough, leathery nature of the gelatine had been destroyed by the strong tanning effect of the formaline.

I would be pleased if you would sound this note of warning in the "Journal," and ask for further experiments as to the after-effects of such strong tanning agents before passing on these formulae to the public.

I may here mention that the effect of strong alum baths or hardening-fixing baths containing alum and acid has never been like that of formaline.

Should it interest any of your readers, I would be pleased to give them my method of developing plates in the tropics when ice is not available.—Yours faithfully,

Cairns, N. Queensland.

A. CHARGOIS.

[We shall be glad if Mr. Chargois will carry out the offer which he kindly makes in his last paragraph. As regards alum, we do occasionally come across cases of bad film disintegration, due to its use, but they are generally of negatives which have been kept for twenty years or more.—Eds. "B.J."]

FORTHCOMING EXHIBITIONS.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Sec.: John Macdonald, 27, Aberfeldy Street, Dennistoun, Glasgow.

AERIAL PHOTOGRAPHY.—The most prominent announcement of the commercial use of aerial photography is a whole-page advertisement which appears in the "Imperial and Foreign Trade Supplement" of Saturday, December 13, issued from the "Times" office. The advertisement announces the facilities for photographic work from the air of the Aircraft Manufacturing Co., Ltd., Hendon, N.W.9. It is stated that although the aerial photographic department of the firm has been in existence for only a few months, over a quarter of a million pictures have already been sold. The firm is equipped for the photography of factories, estates, towns, etc., from the air, and is issuing a series of view postcards of all the beauty spots in England as seen from an Airco machine.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. V.—As you do not mention the candle power of your lamps it is impossible to say what exposures will be necessary. With about 4,000 c.p. you could do what you require providing that your lamps are not more than, say, 6 ft. from the sitter.

A. C.—The regulation requiring licences for new businesses is to be discontinued at the end of the present month, so there will be no occasion for you to trouble about it. Yes, if the business is not carried on in the correct names of the partners it will be necessary to register. The fee is 5s.

G. B. K.—The result is not bad, but you ought to be able to get rid of the band of reflection running down the middle of the jug. We should guess that this is due to reflection of some part of the camera in the metal surface. And if this is so, covering of the whole camera, barring the lens, is indicated as the means to avoid the defect again.

S. J.—The usual method is to hot roll the prints, after dipping in methylated spirit, in contact with thin celluloid. A suitable roller is, or was, supplied by Messrs. Fallowfield, 146, Charing Cross Road, London, W.C.2. You can get suitable celluloid, also a cement which can be used instead of hot rolling from Messrs. Rheinlander and Son, New Malden, Surrey.

A. D.—It is necessary to vignette negatives usually by means of a serrated card held in front of the lens at a few inches distance from it. Most of the supply houses, such as Griffin's, of Kemble Street, Kingsway, London, W.C.2, or Marion's, 3, Soho Square, London, W.1, supply fittings for holding the card in position and moving it about as required for the effect and by the subject.

J. H. (Omaha, Nebraska).—There is no satisfactory means of taking out developer stain from clothing. If the fabric is light in colour you can try the effect of mixing a little bleaching powder (chloride of lime) with water to make a stiff paste and add a little hydrochloric acid—just enough to give it a chlorous smell. But this will usually also take out the colour of the fabric, so that the best thing is to try to match up the stain with ink.

J. H. N.—You first require to be a member of the Royal Photographic Society, which is a formal matter. You should write to the Secretary, 35, Russell Square, London, W.C.1, for a form of application. Admission fee is £1 and the annual subscription at present one guinea, although it is proposed to increase it to two guineas after the end of the present year. As regards the Fellowship, conditions are published by the society.

P. R.—We suppose your lens is the 12-in. No. 6 Celor, listed to cover a 9 x 7 plate at full aperture, but this aperture was $f/5.5$, not $f/4.8$. The pre-war list price was £17 10s. If the lens were in perfect condition it ought to fetch pretty nearly its pre-war list price, but a conspicuous scratch, even if the performance of the lens is all right, can easily reduce its value to a direct purchaser to something like £10.

C. A. G.—We are sorry we cannot turn up any instructions for the use of the "Palmas" camera, and if we could they would probably not be reliable for your purpose, since the table of speeds, according to slit-width and spring tension, probably varies considerably with each size of camera. We suggest that you either write to Messrs. Ross, Ltd., 89, Great Castle Street, London, W.1, who have taken over Messrs. Zeiss's stock, or else send the shutter for the speeds to be tested to the National Physical Laboratory, Teddington, Surrey.

G. M.—We remember the Heyde actinomometer which was on the market a year or two before the war. It never had much sale, and now we are unable to turn up the precise method of using it. The general principle is to look at the deepest shadows of the subject through the hole in the instrument and to move a wedge-shaped screen until you can just not see the shadow detail. This position of the scale is supposed to tell you what exposure to give with a given stop and speed of plate. We do not think that this system is anything like as reliable as an ordinary exposure meter.

A. C.—You can certainly manage with the premises you sketch, but we do not think you have planned out the space to the best advantage. We should suggest making quite a small dressing-room and using the rest of the space next the passage as a dark-room. Then you could put your background close to the window enclosure, and get the full 24 ft. for the studio. We do not like the idea of folding doors. At night or in bad weather it will be unpleasant for the operator as well as for the sitter, and in daytime they will admit too much light and interfere with your artificial light.

L. R.—The double exposure has nothing to do with the covering of the lens, but arises simply from the fact that in posing the sitter twice one image has encroached on the other. You should draw a fine pencil line straight down the ground-glass screen, and then take care that each pose comes just sufficiently to right and left of it. If you use a very dark background you don't need to use a shielding shutter on the lens at all, but if the background has any pattern you, of course, need to do so. If you fix the shutter about 1 in. or 2 ins. from the lens you will have no difficulty in vignetting one exposure nicely into the other.

O. O.—There is always a lot of difficulty in getting rid of pattern when using these filament lamps, especially with large condensers. The only suggestion we can make to improve the conditions which you describe is to use an objective of longer focus, though still, if you can, of large aperture. A longer focus lens in conjunction with a ground-glass screen as close against the lamp as you can put it may get rid of the trouble, although it is doubtful if it will. The fact is you are trying to work a very difficult system, and would do much better with a small arc lamp such as one of those of the Westminster Engineering Co., Victoria Road, Willesden Junction, London, N.W.

A. J.—A supplementary lens increases the relative focal aperture by decreasing the focal length and therefore upsets the focussing scale. In the case of such a very short focus as 3 ins., made still shorter by the use of the supplementary lens, no doubt this would not matter very much for subjects for which the camera is used at the infinity extension, but the scale markings for the nearer distances would be useless. From a practical point of view we think a much better plan, if it is a vest-pocket Kodak, would be to have an adapter for it to take plates. This, if you use the ultra rapid plate, would reduce exposures two or three times. The plate adapter is a little accessory supplied by the Paris firm of Tiraaty, and recently noticed in the "B.J."

E. B.—We think that you will find a total of 2,500 c.p. hardly sufficient for rapid exposures. We should recommend four 1,000 c.p. lamps. It would be better, we think, to rely upon reflectors for lighting the shadow side, starting with the first lamp opposite the centre of the background and the others in a curve, the last one being nearly opposite the edge of the background. You will find some useful information in the article published in the "B.J." of February 7 last. The subject has not been dealt with in any recent "Almanac," and there is no book specially devoted to the subject. If you can manage it, arrange for the lamps to be raised and lowered, as you will find that for sitting figures and children you will shorten exposures by bringing the light nearer the sitter.

F. S.—We are very sorry we cannot throw any light on the spots in the blotting boards, for this is the first instance that we have had, and we are at a loss to account for the spots. We do not think it conceivable that properly made sulphide-toned prints could be spotted through being laid on blotter which is defective in the way yours appears to be, and vice versa it is most unlikely that the blotter would become spotted by the action of the wet prints only. We think that the most likely explanation is that the blotter has got certain defects in it in the shape of spots, and that

these are made visible by the continued presence of moisture, but we do not think there is any real connection between the spots on the blotter and those on the print. We think your best course would be to return the blotters to the makers, preferably after making a further test in the shape of simply letting the blotter (without prints) remain slightly wet for a few days and seeing if any spots develop.

F. L. S.—1. The "Bran" of Wahltech Smith and Co. 2. Nothing better than the use of a serrated vignetting mask held between the lens and the paper. 3. Certainly best in front of the lens, where it can be readily adjusted as regards distance from the lens, etc. 4. Very little to choose between the various leading makes on the market. 5. Distance of the bolting silk from the paper makes a great difference to the results. If you put it quite close you simply impress the pattern of the silk on the enlargement; it requires to be an inch or two from the paper by having it mounted upon an open frame of suitable depth. 6. A matter of expediency or economy. Both methods are very commonly used. The cheaper class of studios regularly go in for enlarging. 7. Probably you have not followed the directions exactly in making the mixture of sulphite and metabisulphite. For the best results this solution should be boiled before dissolving the pyro. 8. On the whole there is no better developer for portrait negatives than pyro-soda. If used weaker (more water) it will give any degree of softness, and vice versa of vigour if used stronger.

R. T.—(1) A long-focus lens—that is, a lens of long focal length—is one which requires a relatively great distance between the lens and the plate when photographing in the ordinary way. For example, 16 in. focus for a half-plate camera would be reckoned a long focus. A short-focus lens is one requiring a relatively short distance—for example, 5 or 6 in. in the case of a half plate. The effect of long focus is to give a large size reproduction of whatever you are photographing and at the same time to include relatively less of the subject; with a short-focus lens you include a very great deal more on the plate, but it is all on the smaller scale. (2) A lens is either fast or slow, according as the largest stop is large or small compared with the focal length. That is, if the diameter of the stop is as much as one-quarter of the focal length, it is a very rapid lens, and is called $f/4$, whereas if the diameter of the stop is as little as $\frac{1}{16}$ th the focal length, that is a relatively slow lens of $f/8$ or $f/16$. (3) Unfortunately, all the elementary text-books on lenses are now out of print, but you could get second-hand from a firm like Messrs. Foylo, 121, Charing Cross Road, London, W.C.2, either "The Lens," by Brown and Bolas, or "Photographic Lenses," by Beck and Andrews, the price (pre-war) being 2s. 6d. and 1s. respectively.

Net Prepaid Line Advertisements.
Charges for Insertion.

12 words or less 1/-
Extra words 1d. per word.
(No reduction for a series.)

Special Note. Advt's. under a Box Number.
"Box No." and office address ... charged as 6 words.
For forwarding replies add .. 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Orders to repeat an advertisement must be accompanied by a cutting or copy of the announcement as previously printed. Advertisements are not accepted over the telephone or by telegram. The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue, but the insertion of an advertisement in any definite issue is not guaranteed.

Cheques and Postal Orders should be crossed " & Co." and made payable to HENRY GREENWOOD & Co., LTD.

DEPOSIT SYSTEM.—When selling goods to strangers, or purchasing, all risk is avoided by employing our deposit system. Cost is trifling. The purchase-money must be deposited with the publishers, HENRY GREENWOOD & Co., LTD., 24, Wellington Street, London, W.C. 2, and all Cheques, Money Orders, &c., made payable to them. Acknowledgment is sent to both parties, and deposit is held until receipt of advice that goods have been received and found satisfactory. In which case the amount deposited is forwarded to the seller, less a commission of 2½ per cent.

To prevent delay communications relating to Advertisements and general business affairs should be addressed to the publishers. All advertisements are received subject to their approval or revision, and the right is reserved to refuse any advertisement without giving a reason for so doing. The publishers are not responsible for clerical or printers' errors, but every care is taken to prevent mistakes.

HENRY GREENWOOD & CO., LTD., Publishers, 24, Wellington Street, LONDON, W.C. 2.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in publication of their announcements.

(minimum, one shilling; maximum, two shillings and sixpence). If goods are not approved the publishers wait original owner's acknowledgment of their sale return before refunding the deposit. In this case the minimum commission only (one shilling) is deducted. All disputes or questions arising from such causes as damage of goods in transit, &c. must be settled between the contracting parties. The deposit is held by Messrs. Greenwood pending settlement. Messrs. Greenwood do not undertake to express any opinion on the condition or value of goods, nor must the goods be sent to them.

Situations Wanted.

A REALLY good Printer, age 32, desires berth with good firm, 17 years' experience; not afraid of work.—Box O. 8, 24, Wellington St., W.C. 2.

C OLOURIST and Finisher (lady), aerograph; 7 years' experience in first-class studio; able to operate; state salary; Manchester preferred.—Box O. 1, 24, Wellington St., W.C. 2.

D EMOBBED soldier, unable to follow former employment, desires situation in good London studio; some experience in the trade; highest references.—"K.," The Priory, Hatfield.

G ENTLEMAN, 25 years' good experience, desires berth as Operator-Manager.—23, Swallowfield Rd., Charlton, S.E. 7.

O PERATOR (27), assist general, retouch, enlarging, framing, sepia work.—"S.," 19, Cecil Rd., Ilford, London.

O PERATOR or Operator-Manager, good middle-class; take entire charge; many years own business; also outdoor work; start at once; any part of country; salary £3 10s.—Wilson, 58, Grosvenor Rd., Newcastle-on-Tyne.

O PERATOR-RETOUCHER, all-round experience, disengaged shortly; good refs.; London or near.—Box O. 7, 24, Wellington St., W.C. 2.

R ECEPTIONIST, educated woman, considerable experience photographic business, good correspondent, accountant, desires engagement as receptionist-secretary to lady photographer.—Box O. 6, 24, Wellington St., W.C. 2.

R EPRESENTATIVE, professional photographer, covering Lancashire, Yorkshire, Potteries, and Lincolnshire, is open to accept agency on commission only for photographic apparatus, plates, paper, or chemicals.—Box M. 8, 24, Wellington St., W.C. 2.

Situations Vacant.

C OMPETENT Lady Retoucher-Finisher required, skilful with aerograph, and with original ideas for sketch backgrounds; good colourist and capable of operating in principal's absence; only those requiring permanency please apply.—Allwork, Tonbridge.

L ESSONS.—Negative Retouching, B. & W., Colours, Miniatures, Operating, Posing, Lighting; slow retouchers, artists quickened, improved; lessons, day, night post (all countries); B. & W. pupils taught "Aerograph," retouching pupils "Nefafake" erasing (knife substitute). This paper's Editor stated re a pupil's work: "We congratulate both tutor and pupil."—T. S. Bruce (Rewriter Standard work, "Johnson's Retouching"), 4, Villas-on-Heath, Vale, Hampstead, London, N.W. See pp. 27-30, "B.J." Almanac, 1914.

O PERATOR wanted for branch studio; must have first-class experience.—Apply, with specimens, and state terms and experience, to Lafayette, 160, New Bond St., W. 1.

R ECEPTIONIST-FINISHER, for highest-class Surrey business; well experienced; preferably over thirty.—Box M. 15, 24, Wellington St., W.C. 2.

R EQUIRED for high-class photographic studio in the East, an Operator-Retoucher; single man only, with highest references.—Apply, "Studio," Henry S. King and Co., 65, Cornhill, London, E.C. 3.

S CIENCE for Photographers.—A series of twelve lectures on Elementary Chemistry and Optics, on Friday evenings, at 7; fee, 12s. 6d.—The Polytechnic School of Photography, 309, Regent St., W. First lecture January 9.

Businesses, Premises, and Partnerships.

A BBOETT, BOOTY AND CO., Business Agents. Consulting Photographers and Valuers, 40 years' experience at your service.—11, Clarence Ed., Croydon.

A BBOETT, BOOTY AND CO. offer Businesses in London, Norfolk, Herts, Yorks, Northants, Sussex, S. Wales, Midlands, and Kent.

A BBOETT, BOOTY AND CO. offer a very profitable high-class Business; £10,000 required; suit capitalist or small syndicate.

A HIGHLY successful middle and good class business, country town, 20 miles London; turnover £1,000; tastefully decorated studio, seven-room house, garden; proprietor wishes exchange with similar or approaching concern; must be on or within 30 miles coast; or would buy; strictest investigation given and required.—Box O. 5, 24, Wellington St., W.C. 2.

G OOD-CLASS Photographic Studio required at Brighton, with living accommodation preferred; about £300.—Write to Mr. Brabazon, Studio, 34, Grafton St., Dublin.

P HOTO, 19 years' exp., age 36, ex-service man, wants management, branch or otherwise, view to purchase or partnership.—Box O. 4, 24, Wellington St., W.C. 2.

S PLENDID opportunity to make money, in most prominent position in Oxford Street, shop and basement, 60 ft. long by 12 and 28 ft. wide, for sale, established 18 years; unique apparatus; low rent, 4½ years' lease to run; Studebaker touring car; price £3,500.—Apply, 37, Oxford St., W.

W ANTED, Portable Daylight Studio, in sections, size about 20 x 12 ft., must be in good condition.—Particulars to Bevan, Star Inn, Wick, near Cowbridge, Glam.

Apparatus For Sale and Wanted.

A EROGRAPH outfit for sale, also 1-pl. Enlarger, for gas.—42, Willow Way, Didbury.

A LDIS 1-pl. Lens, F. 6, 8-in. focus, in Bausch-Lomb's compound shutter, £8. Houghton's Special Portrait Lens, F. 4, 9-in. focus, Waterhouse stops, £3. Watson Studio Stand, F. 2, £3 10s. Two Backgrounds, 6 x 8 and 8 x 8, 12s. and 15s.—Fitch, Marks Tey, near Colchester.

C ONDENSER, 12-in. diameter, new condition; best offer accepted.—Box O. 3, 24, Wellington St., W.C. 2.

S OFT-FOCUS Lens, not used, No. 1 Dallmeyer-Bergheim, £7 10s.; seen at "Sinclair," 54, Haymarket, London, S.W. 1.—Box O. 2, 24, Wellington St., W.C. 2.

S OHO Reflex, brass-bound, teak, Tropical model, 5/4, with reversible back and Goerz Dagor lens, McKenzie Wishart adaptor, scarcely used, £23. "Upavon," Princes Park Avenue, Golder's Green, N.W.

V OIGTLANDER Euryscope Series III, No. 4A, 11-in. focus, good cabinet or whole-plate group lens; flange stops and hood complete, £6. Geiry Studio Shutter, for use with same, 25s. Seen by appointment.—Parker, 52, Yerbury Rd., N. 19.

W ANTED, Cooke Portrait Lens, Series II A, 15-in. focus.—Berry, Hudson St., Rochdale.

W ANTED, Cinema Camera, any make, in repairable condition.—State price and particulars to Rutherford, 85, Alderney St., London, S.W.

W ANTED, Cooke Portrait Diffusion Lens, S. 5, Series II A, 10½-in., with flange, 1-plate and 13 x 18 cm. Negative Storage Boxes, also 12 plate Developing Tanks for same sizes.—Browne, 99, Honor Oak Park, S.E. 23.

Apparatus—Trade.

B ACKGROUNDS, Backgrounds, Backgrounds. Satisfaction guaranteed or money returned. See my lists, 5 stamps.—Pemberton's, Rishton, Blackburn.

B ACKGROUNDS, splendid values. Woodlands, Gardens, Conservatories, Interiors, Sketches. Grounds, 8 x 6, 21s.; 8 x 8, 22s.; other sizes, 8 x 6 white grounds, 15s.; designs, 4d.—Hocking, Artists, Church, Lancs.

C OMPLETE Set of original Stickyback Apparatus. Camera, one slide to take 60 on, printer seat racks numbering to 500, two dishes, lead-lined tank, pedestal, lens, £25 the lot; Dallmeyer Studio Portrait Lens No. 3B, in splendid condition, £15; Dallmeyer No. 1A Portrait Lens, F. 4, with Waterhouse stops, £10 10s.; Ross Goerz Patent 14in. Anastigmat, F. 7.7, with Iris stops, in new condition, £16; Ross No. 6 Symmetrical (8-in.), with Iris stops, £2 15s.; Ross No. 7, Symmetrical (9-in.), with Waterhouse stops, £2 10s.; Busch Lens, Anastigmat Ser. III., No. 23, F. 7.7, foc. 6 in., in new condition, £8.—Apply, E. Mather and Co., Ltd., 7, Victoria Bridge, Manchester.

P HOTO Microscope by Zeiss or Voigtlander with large 50 mm. tube and accessories wanted. State price and details.—"M.," 52, Cambridge Av., N.W. 6.

P OSTCARD Panos Focal-plane, Ross F. 6.3, Homo., 3 D.D. slides and case, £14; 1-pl. Ernemann Focal-plane, F. 5.5 Anastigmat Lens, 2 D.D. slides and case, £15 18s. 6 x 4 Goerz Anschütz, latest pattern, Dagor, F. 6.3, 3 D.D. slides, extension back, roll holder and case, £15 15s.; 10 x 8 Field Camera, all movements, 3 D.D. slides, £6 15s.; 1-pl. Triple Victo-Beck Sym. Lens, T.-P. shutter, tripod, 3 D.D. slides, £7; 8½ x 6½ Triple Imperial Dallmeyer Lens, 3 D.D. slides, tripod and case, £10; 1-pl. Enlarger, 6-in. condenser, carrier, incandescent outfit, £7; 1-pl. Enlarger, 8-in. condenser, carrier, and incandescent outfit, £9; 7½-in. Busch Ommar Anastigmat, F. 6.5, £6; 8½-in. Aldis F. 4.5, sunk mount, £9; 6-in. Ross Homocentric, F. 6.3, focussing mount, £7; 17-in. Ross Telecentric, F. 5.4, iris mount, £22; 11-in. Plano convex condenser in mount, £7 10s.—C. Baker, 244, High Holborn, London, W.C.

R EPAIRS.—Alterations or Special Apparatus to Specification.—H. T. Ball and Co. (17 years with J. F. Shew and Co.), 51, Berwick St., London, W. Only thoroughly expert workmen employed.

T HE Best Market to Buy, Sell, or Exchange Photographic Apparatus; large selection of reliable apparatus always in stock; supplied on liberal approval terms.—Write, stating requirements, to the Westminster Photographic Exchange, Ltd., 119, Victoria St., and 111, Oxford St., London.

V ICTOR Bevelers, simplest, quickest, cheapest: Best, 15 25s., 21 30s. net.—Postal address, Victor Co., Enfield Highway, N.

COOKE PORTRAIT LENSES

That freckled face

EVERY retoucher knows the labour involved in connection with freckled and bad skins, the grain may be good, the modelling skilful, yet the resulting print will always betray these facial imperfections, and considerably reduce the satisfaction of the sitter in the portrait.

COOKE PORTRAIT LENSES

provide a remarkable remedy if the diffused focus device (at the front) is used, the degree of diffusion being entirely under the control of the operator. This does not mean loss of definition, but a soft roundness is imparted to the image which is quite distinct, and materially differs from that obtained from the usual portrait lenses.

*Have YOU got the
 Cooke Portrait effect
 in your photographs?*

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will be placed there whenever its regular position is required for notices relating to the forthcoming "B.J. Almanac."

Partly by Way of Apology.

THE forthcoming "Almanac" is being issued in an edition of 25,000 copies. Owing to the disturbance of photographic conditions during the period of the war, and also to the enforced restrictions in the supply of paper, it was necessary during the last few years to issue only 15,000 copies, a number which we know was a great deal short of the demand.

In restoring the edition to its pre-war figure of 25,000 copies, it would seem that our publishers have taken a somewhat conservative view of the demand for the first post-war "Almanac." Although more than a month has still to elapse before the day of publication, practically the whole of the edition has already been ordered by firms in the distributing trade.

It is therefore necessary that we should make the most definite announcement to those who wish to make sure of obtaining a copy. It requires to be understood that the "Almanac," unlike many other books, is ordered by dealers for chance sale only to a very limited extent. In by far the majority of cases the order to our publishers is based on the individual applications made to dealers for the supply of a copy immediately on publication. Thus, unless this course is followed by the individual purchaser, it will probably be found, on the day of publication, that the copies at a given dealer's are bespoken, and the would-be purchaser is pretty certain to be disappointed.

We would, therefore, ask all those who wish to obtain a copy of the book to place their order now with the photographic dealer, bookseller, or railway bookstall in their neighbourhood. It is particularly requested that these single orders should not be sent to our publishers for execution by post, since the few copies of the edition still remaining undisposed of will probably have been allotted to distributing firms by the time this notice comes before the reader.

EX CATHEDRA.

Import Restrictions Illegal.

Photography obtains a fortuitous prominence in the important judgment delivered last week by Mr. Justice Sankey, who has decided that the prohibition of imports into this country by proclamation in virtue of the Customs (Consolidation) Act of 1876 is unauthorised. For the test case in respect to which the judgment was given was one brought by the Crown against a firm of chemical merchants who had imported packages of pyrogallic acid. In seeking to justify the application of the 1876 Act, the Attorney-General, among other arguments, contended that, as pyrogallic acid is used in photography, and as photography is used in war, therefore pyrogallic acid is in the same class of goods as arms, ammunition, and gunpowder, which come within the scope of the Act. We are not interested in stressing the thinness of this argument or in considering the judgment in its relation to a particular photographic requisite. From the point of view of the photographic trade as a whole, it is the large question decided by the judgment which is of importance. Mr. Justice Sankey, in his searching analysis of the history of the Acts concerned, has decided that the prohibition of imports enforced by the Board of Trade is without authority and remains so unless and until the present judgment is reversed by a higher legal Court, or legislation for the same purpose be passed by Parliament. Although the President of the Board of Trade in the House of Commons on Thursday in last week sought to warn importers of the possible effect of coming legislation, the reception of the Anti-Dumping Bill suggests that interference with the channels of trade by the present Parliament is not likely to take any definite form.

* * *

The Colour of the Mount.

When only a narrow margin of card-board was shown round a mounted photograph the colour and depth of tone did not greatly affect the appearance of the print, provided, of course, that vivid colours were not used. In these days, when the mount is usually much greater in area than the print, the colour and depth need more careful consideration, as the common practice of using one tint of brown or grey for all prints often results in spoiling the effect of the work. There are few bromide printers who can guarantee good sepia tones from every class of negative, and much may be done to make a print look its best by using a suitable mounting paper. Even with black and white prints the depth of tone of the mount must be studied, as a delicate pencil-like image may be made to appear washed out by placing upon a dark grey or brown, which would suit a rich print with strong contrasts. A few pieces of various coloured mounting papers and a piece of colourless glass to keep the print flat will enable the most suitable tint to be chosen with the mini-

mum of trouble. A narrow tint mounted under the print sometimes helps to detach the print from the mount, but, as a general rule, such tints are not to be recommended, and they are in consequence falling into disuse.

Overhauling. Now that the Christmas trade is done with, there is time to take a look round and find what repairs and alterations in studio apparatus are needed so as to be in readiness for the coming season. It is too often the rule to let apparatus go until a breakdown occurs, and if this happens to be at a busy time, much inconvenience and even loss may result. Among the points to which attention may be directed are the re-velvetting of camera-backs and dark-slides, the blackening of the inside of the bellows, and the renewal of the pneumatic fittings of shutters. Those who have much trouble with the latter will find the substitution of the "Antinous" wire-cable release for the customary ball and tube to be advantageous. Lens tubes, cells and diaphragms are also all the better for occasional blackening, while the camera stand often needs some little adjustment to insure smooth working. All these things can be conveniently done in the quiet season, when, if necessary, the principal camera can go to the repair shop for a few days without being missed.

Lighting in Winter. Although most photographers are opposed to "dividing" the light in portraiture, it is sometimes helpful to do so in winter when the light is weak, and reflectors cannot be used effectively. If a rather strong effect of light on the face is required, there will often be a tendency to hardness, and this may, to a great extent, be overcome by opening the blinds at the end of the studio furthest from the sitter. This will give a weak general illumination, which will show detail in the shadows without having the effect of cross-lighting. When lighting approaching the Rembrandt style is used this device will be found very useful. With artificial light a white ceiling or screen fixed over the lamp serves very much the same purpose, an excellent example being found in the "Indirect" model of the reflectors used with the half-watt lamps. Some workers prefer to use a weaker lamp to illuminate the shadow side, but with this there is always a danger of double catch-lights in the eyes and an appearance of cross-lighting generally, which is absent if the indirect light is used. If the studio roof is not white a paper screen or white blind must be placed in a suitable position.

Flashlight Exposures. It should not be forgotten when taking flashlight negatives that the distance between the flash and the subject regulates the amount

of power that is necessary to be consumed to give sufficient exposure—that is to say, when using a powder of which 30 grains will give a satisfactory negative of a head at 5 ft. from the lamp, over an ounce would be required if the flash were removed to six times the distance, or 30 ft. away. This can be seen by examining most flashlight pictures of dinners and meetings, in which the near figures will be seen to be over-exposed, while the more distant ones are almost in darkness. This indicates the desirability of firing the flash as near to the subject as is consistent with even illumination of both sides and keeping the flash out of the field of the lens. Some of the most successful results we have seen have been obtained by firing the flash behind a high screen halfway between the lens and the front of the group. Many photographers, when working single-handed, are in the habit of firing the flash on a level with the camera, of course, at a good elevation, and in this case the shorter the focal length of the lens the more effective will be any given quantity of powder.

PROFESSIONAL PHOTOGRAPHY: AN UNSUCCESSFUL APPEAL AGAINST EXCESS PROFITS TAX.

THOSE of us who are of the view that there is no reason why a maker of portraits by photography should not rank as a professional man will derive little satisfaction from the judgment of Mr. Justice Rowlatt in the High Court last week. The judgment was given, as will be seen from the report which we quote from the "Times" on another page, in an appeal by Mr. Hugh Cecil against assessment of his profits during the years ended October 31, 1916 and 1917, for excess profits duty. In several respects no better appellant could have been selected from the thousands of photographers in this country. Mr. Cecil is a young University man, who took up photography as a means of livelihood, and established himself in a studio in Victoria Street in November, 1912. Within a very short time he made a name for himself as a leading exponent of what is commonly termed individual portraiture. His work was, and is, recognised as marked by his own personality, and the relatively few sitters whom he photographed and to whom he supplied portraits at a price which, apparently, is higher than that charged by any other photographer undoubtedly sought his services on account of his artistic gifts. In this respect, therefore, it was possible to draw an exact parallel between his work and that of a painter, and evidence to this effect was, indeed, submitted in the course of the hearing by a Royal Academician. On the ground, therefore, of professional status and occupation, opposition to the incidence of excess profits tax could not

SUMMARY.

The Index to the 1919 volume of the "British Journal of Photography" and of the "Colour Photography" Supplement is presented with this issue. Space has not permitted the inclusion of a title-page to the "Colour Photography" Supplement, but the publishers will be glad to send a copy to any applicant.

Beginning with the first issue, January 2 of next year, the price of the "British Journal" will be threepence weekly.

By the judgment of Mr. Justice Sankey last week, given in a case relating to the importation of a photographic chemical, recent restriction of importation of goods into the United Kingdom falls to the ground. (P. 749.)

In the last of the series of articles which have been appearing during the present year, "Practicus" deals with the elements of retouching, advising as to outfit and giving such first hints as are possible for the removal of various descriptions of defect from portrait negatives. (P. 751.)

On the ground of coming within the exemption from excess profits granted to certain "professions," Mr. Hugh Cecil appealed last week to the High Court from the decision of the Income-tax Commissioners—and appealed unsuccessfully. On page 754 we quote from the "Times" the proceedings in the Court, and in a leading article

on page 750 are bound to express our disappointment at what seems to us the very inadequate arguments advanced in support of the decision.

The first annual general meeting of the Scientific and Technical Group of the Royal Photographic Society was held on Wednesday in last week, when an administrative committee was elected. (P. 755.)

The favour in which British dry-plates are held in Switzerland is the subject of a note by a Geneva correspondent, M. E. J. Glumart. (P. 756.)

In a recent article in the "Photo-Era," Mr. E. L. Harrison shows how the formula for the size of a pin-hole to be used as a lens is deduced, and gives tables for use in practice. (P. 753.)

A note on the mistake of maintaining too little variety in the colours of mounts will be found on page 749.

A method of mounting prints of extra large size by means of an edging of seccotine is described by a contributor to "Assistants' Notes." (P. 757.)

The distance of the flash-powder from the subject necessarily makes a very great difference in the amount of powder required. A hint as to where the powder may advisedly be placed is contained in a paragraph on page 750.

Wellington

Bromide Papers

Made in an extensive range of grades for every photographic printing and enlarging purpose for which Bromide Papers can be used.

WELLINGTON Bromide Papers became famous for their quality in the early days of the manufacture of bromide papers, and the continuity of that quality is the secret of their popularity to-day.

Complete Catalogue on application.

WELLINGTON & WARD,
ELSTREE, HERTS.

London. Paris. Bombay. Calcutta. Etc.

Johnson's **PROFESSIONAL FLASH POWDER**

A thoroughly reliable and efficient powder giving a flash of very great brilliancy and actinic power. It is specially suitable for Banquets, Balls and similar gatherings, owing to the minimum amount of dust and smoke. Johnson's Professional Flash Powder is now supplied in 1 oz. and 2 oz. bottles. When ordering, be sure to mention "Professional" quality.

conceivably have been offered more effectively than in the person of Mr. Cecil. On other general grounds, which to us seem to be those simply of common justice, there was much to be said in favour of his case. It was shown that during the first two years of his establishment as a portrait photographer—namely, in 1913 and 1914—his work was done at a pecuniary loss; for the year ending October, 1915, his receipts and outgoings balanced each other. During the two following years, and particularly in the second of them, he achieved a substantial financial success, and it was in regard to these two years that the assessment for excess profits duty was made in respect to him, and, presumably, at the rate of 60 to 80 per cent. applying to these periods. From this brief statement it will be seen with what great hardship the excess profits taxation affects those who happen to turn the corner and secure profits from an occupation which for several years previously has been followed without profit or at a loss; at the higher scale of 80 per cent. it means that out of profits of £1,000 the State takes £640, and leaves £360 to the maker of them.

Nevertheless, Mr. Justice Rowlatt was unable to distinguish, from the legal standpoint, between the status of a photographer such as Mr. Cecil and that of an "ordinary trade photographer." He admitted he could not define exactly the word "profession" in the section (39) of the Finance Act (No. 2) of 1915, according to which exemption from excess profits duty could be granted in the case of any profession the profits of which were dependent mainly on the personal qualifications of the person who followed it. For the purpose of the case he adopted the definition that

"a man did not exercise a profession unless he exercised an art the profits of which were dependent mainly on his personal qualifications." To our poor uninformed lay mind it seems that he could not have framed a formula more closely descriptive of the occupation which the appellant followed as a means of livelihood; but, after granting that Mr. Cecil "did things in a more elaborate way than an ordinary photographer," he came to the decision that the Commissioners of Income Tax were right in point of law.

We must confess that the arguments contained in this judgment leave us cold. Unfortunately, only the scantiest reports appear in the Press of the defence offered on behalf of the Commissioners of Income Tax in the way of explaining or defining their interpretation of "a profession." Reference seems to have been made to the Law, the Church, and the Medical Faculty, as the three professions in the historical sense, but we imagine it could hardly be seriously contended that these exhaust the list of occupations which in law and in fact are professions. The professions of architect and consulting chemist are two which occur to us as we write, and must, so it would seem, be ranked equally with those of men who deliver their opinions on legal or medical problems. Considering the importance of the case to professional people generally, it is disappointing that no clarifying definition of a "profession" should have emerged from it. From the more restricted standpoint of photographers we can only express our sympathy with Mr. Cecil at the result of his valiant but unsuccessful attempt to introduce a sense of proportion into the mentality of the authorities entrusted with powers of taxation.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).

The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).
Apparatus Repairs and Renovations (July 18).
Posing the Head (July 25).
Intensifying Portrait Negatives (Aug. 1).
Workshop Jobs (August 8).
The Personal Factor (Aug. 15).
The Keeping of Negatives (Aug. 22).
Reduction of Negatives and Prints (Aug. 29).
Leaky Roofs (Sept. 5).
Blinds and Curtains (Sept. 12).
Miniatures (Sept. 19).
Printing Portrait Negatives (Sept. 26).
Wedding Groups (Oct. 3).
Combination Printing (Oct. 10).

Flashlight Portraiture (Oct. 24).
The Question of Outfit (Oct. 31).
Telephoto Lenses for Professional Work (Nov. 7).
Changing Quarters (Nov. 14).
Carbon Printing—I. (Nov. 21).
Carbon Printing—II. (Nov. 28).
Bromide Wrinkles (Dec. 5).
Natural Poses of the Figure (Dec. 12).
The Reproduction of Negatives (Dec. 19).

ELEMENTARY RETOUCHING.

ALTHOUGH it is difficult to give any useful instruction in retouching without personal demonstration, I hope to be able to outline what may be termed the mechanical side, leaving the student to acquire, by the study of good examples of portrait work, painted as well as photographed, that artistic knowledge which will enable him to apply his technical skill to the best

effect. I would, however, caution the beginner against attaching too much importance to the "before" and "after" retouching examples which are reproduced in most books on retouching, as not only does the half-tone process destroy the character of the original work, but, as a rule, in order to demonstrate his powers, the artist usually puts on a great

deal more work than is desirable in ordinary practice. Negatives are sometimes so perfect that no retouching is necessary, and the nearer a retouched negative can approach this ideal the better.

The appliances necessary for retouching are simple and inexpensive: a retouching desk, a bottle of medium, two or three pencils, a glass paper-block, some spotting colour and one or two fine sable brushes, and a retouching knife.

Next to the pencils, the desk is the most important item in the outfit, and if the beginner cannot afford to buy a fairly large and substantial desk, he will do well to make a rough one by taking a shallow box about 18 ins. square, such as is often used for packing large negatives in, cutting a hole 3 ins. square in the lid and hinging it to the body. Struts must be fitted so that the negative stands at an angle of about 60°, and a black cloth hood, supported by a wire or cane frame attached so as to exclude all light except that passing through the negative. I specially caution the novice against using the small desks a foot or less in width, which are listed by most dealers.

A reflector of white card or opal should be so placed that when looking through the opening in the desk it is evenly and well illuminated. When dealing with very dense negatives, a piece of looking-glass may be used as a reflector, but care must be taken to place it at such an angle that only clear sky is seen through the negative. If window sashes or other obstructions intervene, they are likely to cause uneven work. When working at night or in foggy weather, a lamp must be used, but a piece of ground-glass must be placed between the frame and the negative, so that the flame cannot be seen. When electric light is available, it will, of course, be used, but in this, as well as with an oil lamp, a piece of thin bluish paper should be placed under the negative to "cool" the light. An engraver's globe filled with water, tinted blue with nitrate of copper, gives an ideal illumination. Incandescent gas requires no blue screen.

The pencils should be fitted in ever-pointed holders, and three grades are usually employed. Before the war the best leads came from Vienna, and the numbers most in use were 2 (rather soft), 3 (medium), and 4 (hard). The English leads which have taken their place are sometimes marked with the ordinary grades, B., H.B., and H., which correspond approximately with 2, 3, and 4; but sometimes they are not marked at all, so that a trial is necessary to ascertain what you have got hold of. The pencils should be brought to a very fine tapering point, using first the glass-paper block and finishing on a piece of hard drawing paper or even brown paper. While working, a touch on this paper to free the point from medium may be occasionally required. The No. 3 or H.B. grade is the best for a beginner, although an expert retoucher can work more quickly with a softer pencil. Retouching medium is a varnish-like compound, and is needed to give a "grip" to the surface of the gelatine, which is usually too smooth to take pencil. There are several good varieties, the best known being Autotype, Ellis's, and Winsor and Newton's, all of which I can recommend from experience.

When removing negatives from the washing water, they should always be wiped or swabbed with a pad of cotton-wool or a wash-leather, so as to remove any lime or other sediment adhering to the surface. If this be not done, the medium will make the negative more transparent where it is applied, and this will show in printing. Intensified negatives should be covered all over with medium for the same reason; in fact, it is a good practice to coat the entire surface, as it is a very fair protection from the atmosphere. It often happens, when a re-order is wanted from a rather old negative, that it will be found to have faded everywhere except where the medium has been applied.

The medium may be applied by moistening the cork of the bottle by inverting it and then touching the cork with the tip

of the finger, which is gently rubbed on the parts to be retouched, but a better plan is to use an old silk or linen handkerchief, a small piece of which is dampened with the medium and rubbed on the film, the edges being softened off to avoid a mark in printing. Very little medium is necessary, but it must not be polished off too well. In case it is necessary to remove the medium, and, of course, any retouching upon it, this may be done with a soft rag and spirit of turpentine.

Half an hour or more after applying the medium the negative will be ready for working upon, and the first step is to stop out with the sable brush and a little Indian ink and carmine any clear pinholes or circular marks caused by bubbles in the development. Small holes may be filled with a single touch, but larger ones must be finely stippled. It is sometimes recommended to use "opaque" for this work, but I have found it too opaque for use on half-tones. The colour must be applied as nearly dry as it will leave the brush, or it will run on the surface. A very little gum may be added to give a better consistence to the colour if any difficulty is found in this way.

Freckles and all similar defects must be treated with the pencil only, and here we begin to understand that what retouchers call a "touch" is necessary. For freckles, small curved marks sometimes compared to a comma without the dot are often used, but a sort of tangled line made by keeping the pencil on the surface and moving it in small circular touches is sometimes better. Do not attempt to stipple in dots with a pencil, as this takes an enormous time and is not as effective as lines. Do not overdo the touching of freckles: it is better to leave a ghost of them than to substitute a white freckle for the dark one.

Wrinkles are, as a rule, best treated by short, soft interlacing lines following the direction of the wrinkle itself. Never work across a wrinkle or other line in the face. Where shadows have to be lightened, the circular or comma touch may be used; but it must not be allowed to degenerate into the kind of fish-scale texture frequently seen in beginners' work. An expert retoucher will often appear to be scribbling aimlessly on the negative, but in reality he is varying his touch to suit the texture of different parts of his subject, and this object must always be kept in view by the beginner.

Due consideration must be given to the age of the sitter. Children's faces may be smoothed to any extent; young people's almost the same; but as age approaches we must endeavour to preserve the character and to soften the lines and skin texture without destroying them. With elderly ladies we may perhaps rejuvenate them a little, but not at the expense of likeness.

A common failing with beginners is "spotty" working; that is to say, the face shows a number of worked-up areas with spaces between. To avoid this, the retoucher must not dodge about the negative, doing first one feature and then another, but work right down the face from top to bottom, not necessarily pencilling it all over, but doing what is needed as one goes on.

In present-day retouching the knife or scraper plays an important part, as by its use not only lights but shadows can be put into a negative. Awkward outlines of face, neck, and arms may be corrected, large ears reduced, noses straightened, and many other modifications effected which could formerly be done only upon the print. Space does not allow me to deal with this phase of retouching, and for its study I would refer the reader to the new edition of Johnson's "Art of Retouching," which is the most complete work on the technique of the art which has been published.

With the present issue, "Practicus" in the Studio comes to a finish. "Practicus" will hibernate for a time, but hopes later on to renew his discourses when opportunity arises.

Editorial.

"Man, know thyself!" The Greeks accounted this saying of Solon. "Know thyself," as worthy to be inscribed upon the ancient temple of Delphi.

Really we know very little about ourselves. A gentleman of the name of Snook astonished his friends by proving that he, at least, understood what his *name* meant. Snook, it appears—a true British name, albeit not perfectly euphonious or picturesque—has as its derivation the quite pleasing name "Seven Oaks." The original Snook, you see, had dwelling nigh unto the Seven Oaks, in some delightful old-world village or other. After him, it appears, came "Sennooks," and thus later "Snook."

Do you know what *your* name means?

The Normans appear to have given us all our best names. It is not until after the Battle of Hastings that we hear of our ordinary and usual names. After the coming of the Normans we learn of the Roberts, Richards, Rolands, and Mileses (a soldier) with various modified forms. Thus from Robert came Robertson, Robbins, Dobbins, Dobbs, Dobbinson, and Dobson. Richard passed on to us the Richardsons (the sons of good Richard), Richards, Ricks, Dick, Dixon, Dickens, Dickenson, Hicks, Higgins, and even Hitchcock ("cock" meaning a pert or impudent young fellow).

Another name more prominent about this time appears to have been John, Johnson, and the derivative Jones (the host of sons of sturdy John). This fine name in its various other forms of Jenks, Jenkins, Jennings, Jack, Jackson, Jacox, the Welsh name Evan or Evans, and the Flemish Hanson, Hankins, Hancock, and Little-John, gives the Smiths a really hard race to keep first place.

Outside of "son," one of the most fertile sources of our family names must have been the nickname given in recognition of some good quality, or for a worthy or noble disposition. What finer names can there be than those which pass down for ever the inherent good-qualities of those who bore them first?

Take but a few examples: think of the dispositions of the first good fellows who were named Noble, Swift, Goodman, Wise, Sage, Just. Visualise for a moment the first proud bearers of the names Armstrong, Strong, Doughty. Though the bad that men do lives after them, the descendants of men called by their fellows Noble and Good need not feel that they possess undesirable names.

And now for a moment think of the name of a *product*—yes, of a famous and universally bought and praised photographic plate—IMPERIAL. This name has its meaning. Look it up, pray, in your dictionary.

THE IMPERIAL DRY PLATE CO., LTD.,
CRICKLEWOOD, LONDON, N.W.2.

IMPERIAL FLASHLIGHTS

THE FASTEST PLATES IN THE WORLD

FOR dull weather photography "Flashlights" are invaluable, as by their aid it is possible to make satisfactory pictures under the worst conditions. They are not only high in speed, but they possess also those unique properties which have for nearly a quarter of a century been associated with Imperial plates, and which are known as

IMPERIAL QUALITY

SPEED!

Speed is the vogue of the hour. We whiz by train at sixty miles per hour, and by aeroplane we would fain fly at ninety. And for winter photography—why, *Speed* is still what we need and want. And why not, if you can have quality too?

For every want there is an Imperial Plate—and always, plus, the unequalled *Imperial Quality*.

For fine fast workers who want fine fast plates we supply the now famous Imperial Flashlight. Speed 400, plus unique *Quality* Imperial Flashlight Plates are sold in their hundreds weekly to London's leading Press Photographers and Flashlight Experts. Never have we known the sales of Imperial Flashlight Plates to be so heavy as at the present time. Fine proof for you, if proof were wanted, that "*Imperial Quality Counts!*"

As the name Flashlight implies, the plates are of exceedingly high speed, fast

enough for fine photography, and nearly fast enough for freak-fast photography. Workers of experience who use these plates say that for speed, consistent with really high-grade quality, no plates in the world can equal Imperial Flashlight.

Remember, please, the speed is 400 H. and D. with Imperial QUALITY PLUS.

WHAT DOES YOUR NAME MEAN ? ? ? ?

See Editorial on this page and please do not omit the dictionary experiment.

A "PAWL" Printer

PRODUCES PERFECT PRINTS, QUICKLY.

Price List

"Pawl" Bromide Strip-Printing Machine, complete for electric light **£10 10s.**

Do. do. for gas **£11 15s.**

The table shown in the picture above costs **42s.** extra for either machine.

THERE is nothing you need for your workrooms so much as a "Pawl" Printer. The money you save in time and materials—both very expensive items in these days—soon pays for the cost of a "Pawl." Your assistants will be delighted with it because the "Pawl" Printing methods enable them to get through their work so rapidly and with so little bother.

To the Professional Photographer who cannot get all the assistants he could do with, the "Pawl" Printer is a veritable blessing. It enables the short staffed studio to work happily and sweetly even during a busy rush.

Will you come and let us show you what "Pawl" can do ?

If your business is a big one you can use half-a-dozen "Pawls" profitably.

If your business is a small one then "Pawl" will help you to make it bigger.

If your business is a "one-man" concern you can double your output and save yourself no end of time. One man and a "Pawl" can get through no end of work. Why not get one now ?

PINHOLE PHOTOGRAPHY.

[Those who take an interest in lens optics, and also in the making of photographs, will appreciate the motive which has prompted the contribution of the following article to the Boston journal, "Photo Era." Mr. Hamson usefully traces the derivation of Rayleigh's formula for the size of the pinhole, and shows by the photographs which our contemporary reproduces that pinholes made in approximate accordance with it are very satisfactory in practice.—EDS. "B.J."]

Five thousand years ago the Egyptian astrologer, standing at the bottom of his stone observatory shaft, situated with mysterious precision in the side of a mighty pyramid, studied the celestial image thrown upon his tablet by the converging rays from an orifice in the stonework. That he made use of the data afforded by this primitive camera is certain. And there is reason to believe also that some sort of photographic impression was retained for reference.

The Babylonian, with his special genius for astronomical observation, also made use of the "pinhole camera," and we find a record of an elaborate contrivance of the kind built for celestial observation at Nimrud.

The Phœnician carried the invention to Carthage; Rome seized upon it, and the necromancer of the Middle Ages revelled in its possibilities, albeit he looked upon it essentially as a means to cajole the ignorant.

Yet the chief astronomers of England and France did not so consider it, and volumes have been written by learned scientists upon its principles and their application.

Lord Rayleigh was fascinated by the subject and devoted much time to study of the pinhole and its properties. Indeed, most of the formulae and tables given herein are worked out from his calculations.

Many interesting articles have been published in the photographic journals regarding pinhole photography, yet the matter does not appear to have been regarded in any light other than as an interesting experiment, and its real possibilities and the scientific principles which underlie its operation have not been featured. As a matter of fact, the pinhole, properly made, is an exceedingly useful addition to any artist's photographic equipment.

An effort may therefore well be made to supply complete data concerning the methods and apparatus used in making them.

The chief characteristic, and, likewise, the principal advantage of the pinhole, is its universal focus and its extraordinary angle of view. Its chief drawback is that time exposures are required. Undoubtedly, the first consideration in the manufacture of such a "lens" is to obtain the maximum definition. When made properly, this instrument will produce work not dissimilar to a first-class semi-achromatic objective, rendering definition sufficient for general purposes.

For the size of the aperture we shall have reference to Lord Rayleigh's formula, and shall endeavour to indicate the calculations and give data for the most useful focal lengths. After having given the theory of the case, we shall show that the apertures given by the scientists may be reduced about 20 per cent., with consequent increase in sharpness of image, and indicate the reason therefor.

The wave-length of blue-violet light, which is the chief light to be photographically considered, is approximately .0004 millimetre.

Diagram A.

Now, in order that the light-wave may pass through the lens-orifice without rebound or diffraction, Lord Rayleigh deduced a formula, which is appended, together with a table of openings worked out from this formula (see diagram A).

The limit of retardation of light being taken at $\frac{w}{2}$, w being the wave-length of photographic light, = .000016 inch, or .0004 mil.

r = radius of pinhole.

d = focal length.

$$r = \sqrt{d w}$$

$$\text{and } d = \frac{r^2}{w}$$

Therefore, the distance from the pinhole to the plate-square of the radius divided by the wave length, say .0004 mil.

$$a p = d + \frac{w}{2}$$

Angle $a d p$ = right angle.

$$r^2 + d^2 = \left(d + \frac{w}{2}\right)^2 \quad (\text{Euclid 1, 47}).$$

$$\text{Therefore } r^2 = \left(d + \frac{w}{2}\right)^2 - d^2.$$

$$d^2 + d w + \frac{w^2}{4} - d^2 = d w.$$

$\frac{w^2}{4}$ is very small and may be omitted,

$$\text{therefore } r = \sqrt{d w}.$$

$$\text{and } d = \frac{r^2}{w}.$$

Therefore, distance from pinhole to plate = sq. of radius + length of wave.

This will give a table for the various focal lengths as follows:—

TABLE B.

N. o. lde Number.	Diameter in inches.	Focal Length.	Diaphragm. f. system.
1	$\frac{1}{32}$	32 in.	700
2	$\frac{1}{28}$	28 in.	640
3	$\frac{1}{26}$	23 in.	600
4	$\frac{1}{24}$	20 in.	560
5	$\frac{1}{21}$	18 in.	460
6	$\frac{1}{18}$	13 in.	440
7	$\frac{1}{17}$	10 in.	390
8	$\frac{1}{14}$	8 in.	350
9	$\frac{1}{12}$	6 in.	290
10	$\frac{1}{10}$	5 in.	270
11	$\frac{1}{8}$	4 in.	250

Dr. Miethe's formula gives similar results. Yet a practical test will soon demonstrate the possibility of reducing the apertures some 20 per cent., with increase in quality of definition. The most probable explanation of this seems to lie in the supposition that the "pinhole lenses" used by the scientists were drilled straight through a thin sheet of metal, whereas those used by the author were drilled straight through and afterwards reamed to a knife-edge, therefore avoiding rebound and consequent diffraction. At any rate the best results were obtained with the sizes given in table C.

TABLE C.

Focal Length.	Pinhole-Aperture for Maximum Definition.	Allowable Limits.
3 in.	$\frac{1}{100}$ in.	$\frac{1}{70}$ to $\frac{1}{120}$
3½ in.	$\frac{1}{90}$ in.	$\frac{1}{65}$ to $\frac{1}{110}$
4 in.	$\frac{1}{80}$ in.	$\frac{1}{60}$ to $\frac{1}{100}$
5 in.	$\frac{1}{75}$ in.	$\frac{1}{55}$ to $\frac{1}{95}$
6 in.	$\frac{1}{70}$ in.	$\frac{1}{50}$ to $\frac{1}{90}$
7 in.	$\frac{1}{65}$ in.	$\frac{1}{45}$ to $\frac{1}{85}$
8 in.	$\frac{1}{60}$ in.	$\frac{1}{40}$ to $\frac{1}{80}$

The pinhole objective, once completed, will permit the use of any form of camera. The reflecting camera may be utilised by making a twin lens, with one opening of the regulation pinhole-

size, and the other about 1-16th of an inch in diameter for focussing.

There is no doubt that really excellent and, in some cases, unusual results can be obtained with the pinhole in the hands of a competent photographer. Recently the second prize in a southern competition was won with such means, the judges thinking they were awarding the prize to the possessor of a high-grade semi-achromatic lens.

Landscapes with a lacy foreground and excellent perspective may be obtained if the day is not windy. For architectural work the absolute rectilinearity, the uniform definition and extensive angle of this natural "lens" are very desirable.

Another advantage grows out of the twenty or thirty seconds exposure that are required. A picture in congested regions may be made with calm disregard of the passing public, as they will not be recorded on the plate.

As the size of the image varies directly as the focal length, we find :

$$\text{Size of object} \div \frac{\text{dist. obj. to pinhole}}{\text{dist. plate to pinhole}} = \text{size of image.}$$

Example: Focus 6", object 30' distance, 10 feet high.

$$120'' \div \frac{360}{6} = 2'' = \text{Height of image.}$$

Regarding wide-angle work, a $3\frac{1}{2}$ -in. focus lens on a 10 x 8 plate yields an angle of 142 degrees, which compares favourably with the best wide-angle lenses. However, the lens must be perfect, and mounted specially to get this extreme angle.

Exposures are not difficult to figure out, but can scarcely be guessed. Instituting a comparison between an $f/4.5$ lens and a pinhole $1/50$ in. in diameter, we have :

$$\left(\frac{9 \times 50}{4.5}\right)^2 = 10,000$$

or the number of times we must multiply the exposure required of an $f/4.5$ lens. We will assume that the time is $1/300$ second for the latter in good light. This would give a value of 33 seconds, which is a little excessive in good light—due possibly to the fact that no glass lenses are employed and the light travels absolutely unobstructed to the plate. Reduces this exposure about one-third, giving 22 seconds, and it will be found about right for the same conditions as justify an exposure of $1/300$ seconds at $f/4$ with a fast anastigmat lens.

Regarding the effect of diffraction mentioned above, the author has been unable to discover any trace of this phenomenon in pinholes as small as $1/75$ of an inch, the image continuing to grow sharper to this limit, and remaining virtually unchanged to $1/100$ in., beyond which noticeable loss was shown.

When using anastigmat lenses, the matter is different. Not so very long ago we tested the matter. Knowing that with smaller apertures sharper definition and greater depth of focus were obtained, we decided that if a little was good, more would be much better, and made a number of architectural photographs with a stop of about $f/560$, with results which closely resembled an earthquake in a fog. Upon consulting the authorities mentioned above, we found they had collected all this long before we began, and the allowable limit is set at $f/72$, or thereabouts. At this juncture in our proceedings we returned the volume to the public library, with our benediction. Sometimes science is very annoying. It has no sense of humour at all.

EDWARD LEE HARRISON.

FORTHCOMING EXHIBITIONS.

December 20, 1919, to January 24, 1920.—Scottish Photographic Federation. Sec. : John Macdonald, 27, Aberfeldy Street, Denshield, Glasgow.

MR. ELWIN NEAME'S NATURAL BACKGROUND.—A batch of specimens of the portraits by Mr. Elwin Neame in which the background is introduced artificially at the time of making the exposure on the sitter are reproduced in the December number of "Pearson's Magazine." In the course of a short article, entitled "The Tank That Takes Photographs," a popular and non-technical description is given of the outwardly visible *modus operandi* by which the combined portrait and landscape are produced.

MR. HUGH CECIL'S UNSUCCESSFUL APPEAL AGAINST EXCESS PROFITS TAXATION.

[In the King's Bench Division of the High Court on Wednesday last, December 17, before Mr. Justice Rowlatt, the appeal of Mr. Hugh Cecil against assessment for excess profits duty by the Commissioners for Income Tax was heard. The following report of the case and of Mr. Justice Rowlatt's judgment are quoted from the "Times" of December 18.—Eds. "B.J."]

The appellant appealed, by case stated by Commissioners for the Special Purposes of the Income Tax Acts, against assessments to excess profits duty made on him by the Inland Revenue Commissioners under the provisions of the Finance (No. 2) Act, 1915, Part III., and subsequent enactments. The assessments were £280 4s., less £112 18s. deficiency in the prior accounting periods—namely, £167 6s. net duty charged for the accounting period from November 1, 1915, to October 31, 1916; and £1,230 10s. for the accounting period from November 1, 1916, to October 31, 1917.

The sole ground of the appeal was that the appellant claimed that he came within the exemption from excess profits duty accorded by Section 39 (e) of the Finance (No. 2) Act, 1915, in the case of any profession the profits of which were dependent mainly on the personal qualifications of the person by whom the profession was carried on, and in which no capital expenditure was required, or only capital expenditure of a small amount.

The appellant's name was Hugh Cecil Saunders, and he carried on business as a photographer in Victoria Street, S.W., in the name of Hugh Cecil. He began business without any capital, and had never had any, as little or none was required by him. He did not advertise. Photography had always been his hobby. As an undergraduate at Cambridge he was interested in it from an artistic point of view, and he exhibited there with success. Later, he was elected a Fellow of the Royal Photographic Society, and a member of the London Salon of Photography, which held exhibitions at the rooms of the Society of Painters in Water-Colours. The studies exhibited were not of a commercial nature, but were sent by persons who treated photography as an art. The photography trade did not submit work to the Salon.

After leaving Cambridge the appellant had no occupation, and his friends suggested that he should take up photography as a means of livelihood. In November, 1912, he took a studio in Victoria Street. He worked at a loss during the first two years of his venture. In October, 1915, his receipts and expenditure were about even. Then—as his work became known—his *clientèle* increased. He did not take a great number of photographs, as he devoted more time than was usual to his work. His charges were high—from $8\frac{1}{2}$ guineas to 10 guineas for a single copy. That was because he studied the sitter and composed the picture in his mind. Then he settled the pose, arrangement, and light and shade, exactly as an artist would do. Some of his best portraits were made with a 5s. camera and a 5s. lens. He always took the photograph. The work was very tiring, and he could only do four or five in a day.

He employed a retoucher, but for the most part he himself did the printing on bromide paper. If a copy were required he would not necessarily do it himself. Usually his work was finished when he had prepared and retouched the negative. He had eight employees—five technical and three clerical. Two of them did the mounting. His total salary bill was from £800 to £1,000 a year. In his absence the work came to a standstill. He had two private residential flats, which constituted the studios.

In 1915 he got a window on the ground floor, which served as a large show-case to display his work. His name was inscribed over the window.

The Royal Photographic Society elected Fellows for technical knowledge or for artistic accomplishment. The appellant had none of the former, but his specimens proved that he had the latter. The Salon included only individuals who produced work of art. The appellant had done one small portrait for four guineas, but he declined to do the ordinary trade photograph.

Evidence on behalf of the appellant was adduced to the Special Commissioners. The Hon. John Collier said that the appellant's work showed great artistic feeling, merit, and individuality; that there was a great distinction to be drawn between the appellant's pictures and ordinary photographs. The appellant in taking one of his photographs followed exactly the same lines that he (Mr. Collier) would follow in painting a portrait.

You must use Portrait Film to know its superior qualities. Try it on a difficult subject — shoot across the light, or even into the light — and you will get good results with

Eastman Portrait Film

"The Surest Dry Mounting Tissue Extant"

THE END OF THE WORLD

contrary to the belief held in various quarters has NOT arrived.

Therefore your need for materials is the same as usual. Perhaps even—as some people consider they have a new lease of life—it may be greater.

To avoid trouble therefore in your mounting department and consequent loss of valuable time and money, to say nothing of spoilt prints, see that your dry mounting tissue is of the finest quality.

In other words see that you have a stock of AKRON, which can be relied upon until the world really *does* end.

AKRON products may be obtained from all Wholesale Houses.

AKRON MANUFACTURING CO., 569, HIGH ROAD, TOTTENHAM, LONDON, N.17.

VITECAS

CREAM CARD 7B.

This is a really delightful cream-tinted card, a colour which makes you realise peace has broken out—such a contrast to the violent creams we had to put up with during war time.

The warm black colour of a “straight” VITECAS print on 7B Cream is most attractive. Make a window show of it.

Samples gladly to Professionals.

APPARATUS—TRADE (continued).

SERVICE COMPANY (LONDON), LIMITED, for New and Second-hand Professional and Press Cameras of every description; complete studio furnishings; studio outfits bought for cash or taken in part exchange for other goods.

SERVICE.—Wanted at once, 12 x 10 Studio Outfit, complete; must be in good condition, with first-class Portrait Lens and stand; any reasonable offer entertained.

SERVICE.—1-1-pl. Hare studio outfit, double extension, 1-1-pl. repeating back, with 4 slides; 1-pl. ditto, with 2 slides; these backs are interchangeable; first-class Portrait Lens, silent movement, single pillar studio stand by Watsons, inside bellows, shutter, ball and tube release. The whole offered in excellent order for £13 10s.

SERVICE.—15 x 12 stand outfit by Brown, double extension, reversing back, offered with 3 double book-form slides and first-class R.L. Lens for 12 guineas.

SERVICE.—Bromide and Gaslight cards, best quality; all surfaces in stock, as used by most professionals; sample hundred, 8s. 6d.

SERVICE.—No. 1 Empire Cinematograph by Butcher, maltese cross in oil bath, silent running; complete outfit with Westminster arc 100-volt motor and adjustable iron stand, the whole offered for 24 guineas. Exceptional bargain.—289, 293, High Holborn, London, W.C.1. 'Phone, Holborn 6480. 'Gram "Admittedly." London.

WANTED, 1-pl. and 1-pl. Enlargers; also vest pocket cameras and triple extension cameras; best prices given for all apparatus, and prompt payments.—Watson's, 84, High St., Sheffield.

Materials.

Notes, Papers, Postcards, Mounts, etc.

A QUANTITY of Bromide Paper, all surfaces, to clear; good brilliant paper; genuine bargain prices, 12 x 10 27s. 6d., 10 x 8 20s., 8½ x 6½ 13s. 6d., 6½ x 4½ 7s. 6d., 6 x 4½ 6s. 6d., 5½ x 4 5s. per gross; c.w.o. only.—Charles Hunt, 15, Hillcrest Rd., Acton Hill, W.3.

A RRIVED, Bromide Postcards, all surfaces, Glossy Gaslight Postcards, 1,000 35s., 500 18s., 100 4s. 6d. Half-plates, speed 300, 44s. gross, 4s. 6d. dozen. Whole-plates, Ultra Rapid, 7s. dozen. Glossy Gaslight Paper, cabinet 5s., 1-pl. 5s. 6d., 1/1-pl. 7s. 6d. ½ gross. Satin Bromide Paper, 1-pl. 5s., 1/1-pl. 7s. 6d. ½ gross. All post free.—Wilson's, Chemists, Wigan.

A TTRACTIVE Business, Stationery.—Write for samples and prices, Roman, Wilton St., Bradford.

A LL Materials offered by us in these columns are guaranteed fresh; you run no risks in sending your orders to us; remember, we are an old-established firm with a proud reputation to uphold; all orders dispatched same day; satisfaction guaranteed.—Burt & Co.

B ANHAM'S Brilliant Bromide Paper.—Glossy 2nds, cabinet size, 3s. 6d. gross, or special quarter gross sample packet, 1s.; cash with order; carriage paid.—Banham, Chemist, Hitchin.

B ROMIDE Postcards, glossy singles only, 35s. per thousand. Matt and Semi-matt in strips, 40s. per thousand, or 10,000 lots 35s. per thousand. Cash with order. Carriage paid per goods train.—Banham, Chemist, Hitchin.

B ROMIDE Papers, clearing to prepare for New Year's stock; highly recommended; genuine bargains; no rubbish offered; you may have a sample if you wish; prices above.—Charles Hunt, 15, Hillcrest Rd., Acton Hill, W.3.

B ROMIDE Postcards, Glossy or Satin, 100 4s. 6d., 500 20s., 1,000 38s. 6d.; strips, 6 on, 1,000 40s. post free.—Lenotype Photo Co., Bearwood Rd., Smethwick.

B ROMIDE Paper, in rolls, 10 ft. x 40 in. 9s.; 25 ft. x 40 in. 20s.; Amidol, 2s. 3d. oz.; Metol, 3s. 9d.; Monomet, 3s. 6d.; post free per return.—Burt & Co.

B ROMIDE Paper, matt, satin, and glossy, splendid quality, giving pure blacks, clean whites, and beautiful tones, 3½ x 2½ 3s. gross, 1-pl. 4s., 5½ x 3½ 5s., 5½ x 4 5s. 6d., 5½ x 4 5s. 9d.; 6 x 4½ 6s. 6d., 3s. 9d. ½ gross; 1-pl. 7s. 9d. gross, 4s. 6d. ½ gross; 8 x 6 12s. gross, 6s. 9d. ½ gross; 1/1-pl. 14s. gross, 7s. 9d. ½ gross; 10 x 8 18s. gross, 9s. 9d. ½ gross; 12 x 10 36 sheets 8s., 28s. gross; 15 x 12 24 sheets 8s., 41s. gross; 20 x 16 12 sheets 7s. 9d., 71s. gross; 20 x 16, rough, 12 sheets 6s. 9d. ALL FREE

1. At all times we are willing to send a complete reply, with information and expert advice, relative to any camera or lens purchase, exchange, sale or other transaction required.

2. Write Now! By return of post, at any time, we will send you full lists of any make of camera, also our own large list of high-class second-hand cameras and lenses, accessories, and all materials, FREE.

3. Write NOW! For many years we have been large buyers, for cash, of good second-hand cameras and lenses. We are at all times willing to quote a CASH OFFER for any GOOD apparatus you can send us. If our offer is not accepted, we return your apparatus, carriage paid. We have HUNDREDS of grateful letters from customers who praise us for the HIGH PRICES WE PAY.

4. Write NOW! We allow free examination and trial of any cameras in our stock. Simply deposit with us the list price, and you are allowed three days' free use and examination. If the apparatus does not meet your requirements, return it, and we refund in full. We also negotiate any kind of exchange as part payment, and our exchanges are said to be the fairest in the trade. Is there any camera you desire to test and examine just now?

5. Write NOW! Send a Postcard to-day for a copy of our Great Bargain List just published. This is what the "B.J." says about our latest Catalogue:—

"Sands, Hunter's catalogue is a piece of trade literature of special importance; in fact, one which no photographer, professional or amateur, can afford to overlook whenever he has a purchase to make."

SEND FOR A COPY TO-DAY.

**Reflex Work with the
Ross Telecentric Lens**

Although the Ross Telecentric Lens is useful in almost every branch of photography, it is probably in Reflex Work that its advantages are most apparent.

The Telecentric Lens gives an image twice as large as that given by an ordinary lens from the same viewpoint. It needs no extra camera extension, and it works at an aperture of F5.4 or F6.8.

The Reflex Worker can realize at once what this means. He can get an image twice the normal size without approaching any closer to his subject, an advantage which can scarcely be overestimated in dealing with Natural History Work, Child Portraiture, Sports, Press Work, etc.

This enlargement does not entail any extra fittings to his camera or any reduction in the aperture of the lens. In short, the Ross Telecentric Lens gives you telephoto results with focal-plane exposures.

Send for full particulars.

MARSHALL & CO., Mansfield Road, NOTTINGHAM

Now is the time of year when the Photographer sets about the making of Lantern Slides from the negatives taken during the Summer. It is a pleasing occupation for the enthusiast during the long Winter evenings, but what is more pleasing still is when the opportunity presents itself to project the slides on to the screen for the instruction and amusement of one's friends. For lantern work the book entitled "The Optical Lantern" is what you want. The price is, in paper boards, 1/6 (post 1/10), or paper covers 1/- (post 1/4). It is published by the Cursitor Publishing Co., 12, Cursitor St., Lond., E.C.4.

R. & J. BECK, LTD.,

68, Cornhill, London, E.C.3.

Mr. F. J. Mortimer, art editor of the "Amateur Photographer," and of "Photograms of the Year," said that he was Hon. Secretary of the London Salon and a Fellow of the Royal Photographic Society. He explained the difference between ordinary trade photographs and photographs such as would be produced by the appellant, which would be accepted by the Salon and the Royal Photographic Society. The appellant's work showed distinct individuality.

It was contended on behalf of the appellant that the business carried on was a profession—namely, that of an artist in photographic work, and not that of an ordinary photographer, and that the capital employed by the appellant was nominal, and that the profits of his business were dependent on his personal qualifications.

On behalf of the Commissioners, it was contended that the appellant was carrying on a trade or business, and that the exception (e) to Section 39 of the Finance (No. 2) Act, 1915, did not apply.

The Special Commissioners considered the whole of the facts and contentions, and they were of opinion that the appellant came within the charge to excess profits duty and confirmed the assessments.

Mr. Holman Gregory, K.C., Mr. Bremner, and Mr. G. Pilcher appeared for the appellant; and the Solicitor-General (Sir Ernest Pollock, K.C.), Mr. T. H. Parr, and Mr. R. P. Hills for the respondents.

Mr. Justice Rowlatt, in giving judgment, said that the case raised the question whether a man who carried on business as a photographer of a special kind carried on a profession within Sub-section (c) of Section 39 of the Act of 1915. It was a commonplace by this time that the word "profession" in that sub-section could not be exhaustively defined, but, for the purpose of the present case, a man did not exercise a profession unless he exercised an art, the profits of which were dependent mainly on his personal qualifications. It was necessary to inquire whether the decision of the Commissioners was erroneous in point of law. It was true that the appellant's work differed from that of an ordinary photographer. He had gone very much beyond the work of the ordinary trade photographer, but he did not, as it appeared to him (his Lordship), do anything in law beyond what an ordinary photographer did. He had great ability in posing his subjects and in seeing where an attractive picture could be made. He did things in a more elaborate way than an ordinary photographer, but it was all a question of degree. It was impossible to decide that the Commissioners had gone wrong. Where it was a mere question of degree, as in that case, the decision of the Commissioners could not be set aside unless they had applied wrong principles or a wrong test. As it could not be said that they had gone wrong in law the appeal must be dismissed.

THE MICROSCOPE: ITS DESIGN, CONSTRUCTION, AND APPLICATION.

The Faraday Society, the Royal Microscopical Society, the Optical Society, and the Photo-micrographic Society, in co-operation with the Optical Committee of the British Science Guild, meeting in joint session, will hold a symposium and general discussion on "The Microscope: Its Design, Construction, and Applications," on Wednesday, January 14, 1920.

The meeting will be held in the rooms of the Royal Society, Burlington House, Piccadilly, W.1 (by kind permission of the President and Council), and it will extend over two sessions: from 4.30 to 6.30, and from 8 to 10 p.m. During the afternoon preceding the meeting from 2.30 to 4.30, an exhibition will be held in the Library of the Royal Society, which will illustrate recent developments in the science of microscopy and the latest applications of the microscope in all branches of industry.

The purposes of the discussion are:—

(1) To stimulate the study of and research in microscopical science in the United Kingdom by:—

(a) Indicating lines of progress in the mechanical and optical design of the instrument;

(b) Showing, by means of exhibits, recent improvements in the microscope and its technique; and

(c) The varied uses to which the microscope can be applied as an instrument of research in the sciences, arts, and industries.

(2) To encourage the manufacture in this country of the highest class of instrument and of the optical glass required for that purpose.

The meeting will be presided over by Sir Robert Hadfield, Bart., D.Sc., D.Met., F.R.S., President of the Faraday Society, who will deliver an opening address, and Mr. J. E. Barnard, President of the Royal Microscopical Society, will then give a general survey of the subject, and he will be followed by Sir Herbert Jackson, K.B.E., F.R.S. Prof. F. J. Cheshire, C.B.E., will then speak on the Mechanical Design of Microscopes, and a paper by Prof. A. E. Conrady on Microscopical Optics will be presented.

Among those who have, up to the present, also indicated their intention of contributing papers and to the discussion are:—Dr. L. Aitchison and Mr. F. Atkinson, Mr. W. B. Appleton, Prof. Dr. Carl Benedicks and Mr. E. Waldon, Prof. H. Le Chatelier, Prof. C. H. Desch, Dr. J. W. Evans, F.R.S., Dr. F. Giolitti, Dr. W. H. Hatfield, Prof. H. M. Howe, Prof. Zay Jeffries, Mr. W. H. Lamplough, Mr. E. F. Law, Dr. A. McCance, Mr. J. H. G. Monypenny, Prof. Alfred W. Porter, F.R.S., Dr. W. Rosenheim, F.R.S., Dr. G. E. Stead, F.R.S., Mr. H. G. Ryland, Mr. H. M. Sayers, M. E. Schneider, Dr. R. E. Slade and Mr. G. I. Higson, Dr. F. C. Thompson, Prof. W. M. Thornton, Dr. M. W. Travers, F.R.S., Dr. A. E. Tutton, F.R.S., Mr. F. Twyman, Dr. R. M. Walmsley, Dr. W. R. Whitney, and Dr. R. S. Willows.

Exhibits will be shown by Mr. Charles Baker, Mr. Arthur Banfield, Prof. W. M. Bayliss, F.R.S., Messrs. R. and J. Beck, Ltd., Messrs. British Dyestuffs Corporation (Huddersfield), Ltd., the Cambridge Scientific Instrument Co., Ltd., Mr. A. Chaston Chapman, Messrs. Courtaulds, Ltd., Messrs. Dallmeyer, Mr. F. Davidson, Mr. R. Finlayson, Geological Survey and Museum, Col. J. W. Gifford, Mr. R. E. Hanson, Dr. W. H. Hatfield, Mr. Albert Henning, Miss Nina Hosali, Dr. Jaeger's Sanitary Woolen System Co., Ltd., Messrs. Kodak, Ltd., Mr. H. C. Lancaster, Dr. Geoffrey Martin, Dr. J. W. Mellor and Dr. A. Scott, Dr. F. G. Ogilvie, Mr. F. Ian G. Rawlins, Mr. W. C. Reynolds, Mr. J. Rheinberg, Mr. J. Strachan, Dr. Marie Stopes, Messrs. James Swift and Son, Ltd., and Messrs. Taylor, Taylor, and Hobson, Ltd.

Further particulars relating to the discussion may be obtained from F. S. Spiers, Secretary, The Faraday Society, 10, Essex Street, London, W.C.2; or C. J. Lock, Secretary, the Royal Microscopical Society, 20, Hanover Square, London, W.1.

THE SCIENTIFIC AND TECHNICAL GROUP OF THE ROYAL PHOTOGRAPHIC SOCIETY.

The first annual general meeting of the newly-formed Scientific and Technical Group was held at 35, Russell Square, on Wednesday, December 17, when about fifty of the members of the Group mustered in the Library, where they discussed tea and cake, and then adjourned to the meeting-room. Mr. W. B. Ferguson, K.C., M.A. (Oxon.), F.I.C., was elected to the chair, and was supported by Messrs. F. F. Renwick, O. Bloch, and Dr. R. E. Slade, who had been acting during the last few months as a provisional and organising committee.

Messrs. Fraser Black and Whitfield Taylor were elected scrutineers of the ballot, and retired with the ballot papers.

Mr. F. F. Renwick, for the provisional committee, said that after the initial meeting steps had been taken to get into touch with all members of the Society, and particularly those who had evinced interest in the proposed work of the Group, about 140 adherents had been secured, and it was hoped that by the New Year the number would reach 200. The subjects in which the members were interested had been tabulated, and a democratic programme drawn up. The council had passed standing orders which gave the Group a constitution, and the provisional committee had drafted by-laws to be discussed and amended, if necessary, that evening, and to be submitted to the council for approval. The initial expenses had been somewhat heavy, but were justified, he thought, by the success achieved.

On the motion of Mr. Slater, seconded by Mr. Sellers, the report was adopted.

The proposed by-laws were discussed *seriatim*, and were adopted with slight alterations. One of these was to the effect that the annual general meeting of the Group should ordinarily be held on the second Wednesday in May instead of on the second Friday in that month. By-law 12 was divided into two parts, and a proviso added to the first that no member might make more than six nominations to the administrative committee. In the second part of the by-law

(now 13) it was provided that nomination papers should be open to inspection by its members. From by-law 20 (formerly 19) the provision for publishing abstracts, etc., in the "Photographic Journal" was deleted. The Chairman volunteered to redraft the by-laws and incorporate the amendments.

The scrutineers, on their return, reported that seventy-four ballot papers had been received (one invalid), and that the following were elected as Administrative Committee:—O. Bloch, F.I.C.; Sir William J. Pope, K.B.E., F.R.S., Hon. F.R.P.S., etc.; F. F. Renwick, F.I.C., F.C.S., A.C.G.I., F.R.P.S.; E. Sanger Shepherd, F.R.P.S.; R. E. Slade, M.C., D.Sc., F.I.C.; G. Whitfield.

The proceedings terminated with a vote of thanks to the chairman.

THE SUCCESS OF BRITISH PLATES IN SWITZERLAND.

WITH the cessation of hostilities and the subsequent waiving of restrictions in regard to exportations came the opportunity of British photographic firms to make good in the overseas markets. At a first glance this did not seem a very easy matter. In certain countries, such as Switzerland, Germany was in the field, and had been so during the whole period of the war; moreover, freightage was cheaper and the mark was low. But with characteristic British perseverance—a perseverance to which, perhaps, credit is not often given—British firms, quite aware of the magnitude of the task, entered the lists in a whole-hearted manner, and in the first onslaught beat the Teuton. The weapon used was quality. One instance, typical of many, will illustrate this fact. A rotary photogravure firm in Geneva, which had for many years employed German plates, was induced to purchase some newly-arrived British plates—an inducement, by the way, which did not call for an exceptional amount of persuasive powers on the part of the agent. With the first exposure a decided improvement was remarked, the negative possessing a tone and vigour not obtainable in the German plate. Further experiments confirmed the excellent result of the first, and as this particular firm have a reputation for good work, a number of negatives and positives previously made with German plates were immediately scrapped and the originals re-photographed with British plates. The remark of the happy director was brief: "They're dearer, but they're worth it." What more need be said?

A pleasing feature of the presence of the British plate in the Swiss market is the activity displayed by the agents in bringing to the notice of the various firms the excellent quality of the wares they sell. This is having the desired result, and will undoubtedly lead to increased sales.

In Switzerland the amount of three-colour work turned out is not inconsiderable, and there are signs that this is increasing. This fact should attract the attention of dealers in panchromatic plates, and the agents would be well advised to set out on a conquest of those firms using collodion emulsion, for, though emulsion has been in general use for many years and in most cases has successfully resisted the advent of the dry plate, there is no reason why the now perfected panchromatic dry plate should not come into its own, even as the ordinary plate has won laurels in photogravure.

The photo-mechanical plate for half-tone and line work is up against a greater proposition, for here, as is probably the case in England, most firms prefer collodion for this class of work, but for certain subjects it may find a ready sale.

There is still an open road to success for the various makes of bromide paper, and though French and Belgian products are in demand, well advertised British bromide or other papers would certainly be given a trial, and a trial is all that is needed.

E. J. GLUMART.

CO-PARTNERSHIP IN THE OPTICAL INDUSTRY.—An interesting pamphlet has been printed by Messrs. Taylor, Taylor and Hobson, Limited, in the shape of a reprint of an address by Mr. William Taylor setting forth the scheme of co-partnership between the firm and its employees. The scheme replaces one of ordinary profit-sharing, and we are quite sure that firms contemplating plans of this kind will be anxious to study the system which has been evolved, after much study, by Mr. William Taylor.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Dry-mounting Prints of Extra Large Size.

WHEN one is used to a dry-mounting press, it is not pleasant to be suddenly faced with a job for which the process is apparently useless and a reversion to the old wet method seems necessary. This is what happens when the size of a mount is such that it will not go between the arms of the press.

Provided that the unmounted print or enlargement is not too wide, paste and starch can still be avoided by dry-mounting the print to a piece of thin pliable art mounting—such as "Nestor," "Baltic," or "Ensign" art boards—doing any necessary trimming afterwards.

A print so backed can be mounted securely and flat with an edging of Seccotine. To do this well the print should be laid face down on a clean sheet of paper, and the nozzle end of the tube passed lightly around, about 1-16th to 1/8th from the extreme edges. To prevent any possibility of the print bulging in the centre, a couple of lines can be run across in each direction (dividing the back of the print into nine sections). The backed and "seccotined" print is laid on the mount in the required position and put under pressure for an hour or two, when it will be fixed perfectly flat and with no tendency to future cockling.

A good border can be made by cutting the pliable mounting a shade larger than the enlargement, taking care when pressing not to damage the edges on the arms of the dry-mounter.—THERMIT.

A Useful Knife.

AN excellent scraping knife can be fashioned out of a wooden-handled pushpin and a small piece of hard wood about the size and shape of an average cigar. For very small and fine work this knife will be found exceptionally useful.

The pushpin is chosen for its blued steel point, which should be as long and thick as procurable. This point is extracted with pliers and with the same tool forced point first about half its length into one end of the cigar-shaped piece of wood. The ferrule is next removed from the original handle, taking care not to split it in the process, and the point of the new handle having been shaved down sufficiently, the ferrule is pressed into place over the steel pin.

We now have a blunt pin on a convenient handle. The next step is to grind the pin down to an oblique edge, which can be done with a file, or much more quickly on an emery or carborundum wheel, finishing off on a whetstone.

Such a knife will scrape the most delicate spots from the toughest film without lifting pieces out.—THERMIT.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Something NEW

Here's a wonderful photographic discovery. It is a printing medium registering the *Vigour* of Gaslight yet possessing the *Speed* of Bromide.

A NEW POWER

It gives a new power to the photographer. Its latitude is enormous, and, with it, enlargements can be made successfully and quickly from the poorest negatives. For topical work it means shorter exposure, for negative difficulties will be overcome by its vigour and its speed

Usual prices. Send immediately for sample to—

Ridley and District Photographic Society. "Colour Photography." C. B. Howdill.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held at 35, Russell Square (the house of the Royal Photographic Society), on Friday, December 12, 1919.

Present: A. Basil, Gordon Chase, A. Corbett, C. F. Dickinson, Alfred Ellis, S. H. Fry, Reg. Haines, Geo. Hana, R. N. Speaight, Lang Sims (London members), Marcus Adams (Reading), Frank Brown (Leicester), W. B. Chaplin (Windsor), T. Chidley (Chester), A. H. Chapman (Swansea), and F. Read (Southport). A letter of regret for inability to attend was read from W. Illingworth (Northampton).

The minutes of the last meeting were read, amended, and confirmed. A report from the Congress Committee was presented, containing a skeleton programme based on 1914 experience. The committee proposed to hold an exhibition of professional portrait work, the object of which would be to illustrate the present position of professional portraiture in the United Kingdom. The amount of space at the committee's disposal would not be large, and it was proposed to obtain the exhibits by invitation. The invitations would not be limited to members of the Association. The committee had a considered scheme, and required the approval and authority of the Council to proceed with it. It was moved by Mr. Read, and seconded by Mr. Chase and carried unanimously, that the report be accepted and full power be given to the committee to continue their arrangements and to report to the Council from time to time.

The Finance Committee recommended for payment accounts amounting to £87, and further recommended that, being satisfied that the present position of the Association's finances justified it, the appointment of Mr. Fry as secretary for the year 1920, which appointment was approved in principle at the Council meeting held on October 23, 1919, be proceeded with, and it was moved by Mr. Lang Sims and seconded by Mr. Chapman that the report be adopted; carried unanimously.

Mr. Lang Sims then moved: "That a subscription list be opened for the purpose of presenting a suitable memento to Mr. Alexander Mackie in recognition of his valuable services to the Association extending over a long period." He said that he was sure that every member of the Council had no thoughts other than kind and

friendly ones towards Mr. Mackie, whose connection with the Association over a long period of years had been one of whole-hearted enthusiasm for its welfare. His work, both in its earlier and later years, had been characterised by thoroughness and conspicuous ability. The new edition of the P.P.A. Handbook, copies of which had but recently been distributed to the members, was only one item of evidence of his painstaking care. Mr. Mackie had been and was very well known to all, and his work had been of great value to the profession as a whole. He (Mr. Sims) moved this resolution with a great deal of pleasure, as he believed it would meet with the approbation of every member of the Association. Mr. Tom Chidley seconded the resolution. He said he was sure the proposal would meet with everyone's approval and support. Mr. Mackie had given useful and valuable advice to many members of the Association from time to time.

After further kindly references to their former honorary secretary, the resolution was put and carried unanimously. The details of the proposal were left for settlement to the next Council meeting.

The hon. secretary reported that the new edition of the Handbook had been posted to members, and he hoped that it would meet with general approval. There was more useful matter in it than before.

His next effort to overcome the arrears left by the war should be to publish a similar brochure containing the names and addresses of the members. This involved a large amount of personal work, and had been and even now was delayed by the continuous returning of members whose subscriptions had been suspended during their war service. A list of members was of little value unless sufficiently accurate, and however carefully done soon became out of date, owing to the natural loss of members which occurred in a large association, and the constant removals and changes of address.

A considerable number—nearly forty—of new members had come in as a result of the publication of an interview with one of the Association's officials in the Kodak house journal, "The Professional Photographer," and with new members from other sources there was now a list of fifty names which had not yet been read to the Council. He was afraid that the total for the current year would not approach last year's total, however. He had to report that the profiteering case brought by a member had broken down owing to the fact that as photographic postcards were not "scheduled" under the Act, the complaint could not be proceeded with as against the manufacturers.

The November number of the Circular had been published strictly to time, and he had received many letters of approval from members.

There had been a considerable correspondence during the month with members, and many complaints and enquiries had been dealt with. Fire insurance enquiries and proposals had increased owing to publicity in the Circular, and he hoped at an early moment to be in a position to offer the Association's special premium concessions to cover motor-cycles and motor-cars. Amongst the month's correspondence were such varied subjects as copyrights and increased fees; the high prices of photographic materials; the bad rail services, especially delays in the matter of empty returns; the non-supply of roll films to professional photographers; an assistants' union; and prices for difficult ortho-chromatic reproduction work.

This being the last Council meeting in the financial year, the hon. treasurer reported that he expected to be able to present a favourable statement of accounts for the year 1919. The expenses of the Association in conducting its business had been greater in the current year, but the income had also expanded in a manner which he believed the Council and the members of the Association would consider satisfactory.

CROYDON CAMERA CLUB.

DESPITE the genial prophecy that December 17 was to wind up the club, and incidentally the world in general, Mr. W. Kenrick, taking all risks, gave a capital lantern-lecture, entitled "The Work and Records of the Photographic Survey and Record of Surrey." At first sight this subject may seem a dry one except to those interested in the work, but he contrived to make it most interesting to all. He showed convincingly how infinitely superior the eye of the camera is to the perception of the artist when it comes to faithful records—not that the former need be necessarily un pictorial—and it is worthy of note that the finest slide, both in technical quality

and artistic representation, was from a film made with a ten-shilling "Browme." Mr. Kenrick's own contribution to posterity consists of 2,000 prints and 900 lantern slides, truly a record to be proud of. Here indeed is photography with a purpose.

During the evening Dr. C. Atkin Swan, F.R.P.S., was elected a member of the club with much acclamation. The "office boy" (proposer) said he recently had had the pleasure of witnessing a private rehearsal of a lantern show with the doctor operating the alternating arc, and a most wonderful imitation of a cinematograph seriously out of order was afforded. If only they could persuade the doctor on some future occasion to operate the club lantern for a peppery lecturer, everybody should experience the time of their lives.

The previous week, Mr Vivian Jobling, with hair cut regardless of expense and looking very trim and spruce, gave an excellent and very practical demonstration on "Staining and Finishing Picture Frames." As a jobbing workman he is hard to beat. He advocated narrow oak frames stained to harmonise with the picture or photograph, as the case might be, or else plain walnut, wax-finished. An extra-special and really ingenious mitre-block was brought forward. In his hands it worked like a charm, and enables the two mouldings forming one mitre to be cut with one sawing, which dispenses with planing true and permits of a better grip for the glue. The mitre-block received unanimous commendation, which is unusual in the club, and even the secretary, Mr. Sellers, failed to suggest any improvement, which is more than unusual. The demonstrator strongly recommended all joins should be screwed as well as glued, for then the frames never showed signs of coming apart, even if continuously exposed to damp.

Many recipes for staining followed. For oak frames he recommended, when a good brown colour is desired—black japan, one part; turpentine, two parts. Paint on, leave for about ten minutes, and wipe off all unabsorbed stain. For a very dark brown—burnt umber, oil-colour, is rubbed into the wood; cheap "students'" tubes answer well. For a green—prussian-blue and burnt-sienna water-colours are mixed and well rubbed in. For a "brindle-brown"—soot and water are incorporated and applied with an old brush, surplus being removed with a wet rag.

For finishing, in preference to plain beeswax and turpentine, he advised—beeswax, 3 ozs.; spermaceti, 2 ozs.; turpentine, 10 ozs. Mr. Rose here differed, stating "oiling up" gave a more chaste effect, but Mr. Jobling stuck firmly to the wax.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

OBJECTIONABLE PHOTOGRAPHS.

To the Editors.

Gentlemen,—All photographers who wish to maintain a clean reputation for their profession should thank you for the strictures contained in "Some Matters of Etiquette" which appeared in your issue of 12th inst.

A certain section of the illustrated Press has for some years pandered to the pornographic portion of the public by publishing prints of the "legs and lingerie" order, with the result that questionable pictures are now accepted quite as a matter of course. People being presumably satiated with the contemplation of calves—shapely and otherwise—the ladies have been induced to undress their upper portions, so that it is possible to acquire an almost complete knowledge of female anatomy by the judicious combination of these two periods of art.

The fact that such things are thrust upon us is, however, no reason why photographers should break away from their legitimate work, and endeavour to secure a doubtful type of clientele by the exhibition of such meretricious productions.

I know of a photographer's window wherein repose a row of "Art studies" (vide label) which fairly shriek "chorus girl with her clothes off"; and, indeed, judicious inquiry discovered this to be the case. The damsels in question are neither pretty nor graceful, and not even the "glad eye" with which they coyly contemplate the observer can compensate for the vulgarity of their ill-formed naked backs and angular arms.

These photographs are exhibited in a busy thoroughfare, yet few women stop to look at them. The moral is obvious, though the photographer is doubtless doing a good, if ephemeral, business in his special line.—Yours faithfully,

OLD HAND.

LENS-SEPARATION IN STEREOSCOPIC PHOTOGRAPHY OF SMALL OBJECTS ON THE SAME OR AN ENLARGED SCALE.

To the Editors.

Gentlemen,—May I offer a few remarks on this interesting subject? I have made a few experiments on paper which seem to offer a basis to work on, for near subjects.

On separation of lenses in stereo camera:—

1. When photographing full size the distance between focussing screen and the object is equal to four times the focal length of lens.
2. The lens will be about midway at twice its focal length.
3. The separation (laying midway) will be about $1\frac{1}{2}$ ins. (say $1\frac{3}{4}$ ins.) whatever the focal length may be.
4. When photographing a landscape the lens would be brought back a distance equal to its focal length (viz., infinity), the separation being anything from $2\frac{1}{4}$ ins. to 3 ins.
5. If we so adjust this difference of focus between a landscape

and an exact size object so that the separation fits it correctly at all places we shall have a ready means of comparing angles and focusses.

6. A 3-in. lens would bring an object full size at 12 ins. from focussing screen (forming an angle at 12 ins. therefrom).

7. A 6-in. lens would extend the object to a distance of 24 ins., forming an angle proportionately.

8. It would appear that for near work the short-focus lenses give the greatest angular relief, and the longer focus less angular relief.

On relief in stereo camera:—

1. It would appear that for objects having few planes, such as a coin relief, the shorter focus might give a better rendering.

2. An object with many planes, such as a pin cushion with pins at many distances, would be rendered better by longer focussed lenses.

I am enclosing a drawing to make it as clear as I can, with a suggestion of making a scale on a lath for each focus of lens in use. This would provide a fairly ready means of finding out or comparing the angle, extension, etc., according to scale of object and getting a particular angle of relief by choosing a certain focus lens.

I am, however, enlarging on this subject in a further letter. This covers the subject in the stereo camera, but thoughts go beyond it.—Yours sincerely,

JOHN WIELD.

Woodhall Spa.

To the Editors.

Gentlemen,—Mr. Benham's diagram clearly shows the principle involved in taking stereos. at close quarters, if the normal stereo-

The British Journal Almanac, 1920.

Edited by GEORGE E. BROWN, F.I.C.

Now in the binders' hands for publication at the end of January or early in February.

The editorial article is titled "Beginners' Failures in Photography," and covers the whole field of photography. It is written in a way to bring it within the understanding of the least experienced.

The fifty-ninth issue of the Almanac, which is restored to its pre-war edition of 25,000 copies, will be found as valuable as ever in the work-room of the amateur and the office of the professional.

The prices remain at 1s. 6d. in paper covers: 2s. 6d. cloth bound. To make certain of a copy, an order should be placed at once with a photographic dealer, bookseller, book-stall, or newsagent.

scopic effect is aimed at; but there are two other considerations: firstly, that if simultaneous exposure is necessary, then the reduced lens separation as shown by this diagram may yet be too great to bring both images on to the one plate; and, secondly, that for scientific purposes it is sometimes useful to get an exaggerated stereoscopic effect by increasing the lens separation. If simultaneous exposure is not essential, is there any objection to swinging the camera direct on to the object for successive exposures of right and left halves?

It will be noted that Mr. Benham takes 2½ in. as his basis, whilst your original correspondent takes 3 in. as the normal lens separation. I am of opinion that such wide separation is a mistake, and is the result partly of the desire for exaggerated relief, partly of the adoption of unsuitable plate sizes and the fixing of lens separation according to these plate sizes rather than on any logical basis.

My earliest stereo. work was done on a 7 by 5 with lenses of 6-in. focus at 3½-in. separation, but now, for a long time, I have worked with 2½-in. separation (the separation of my own eyes) and lenses of 3½-in. focus, latterly on the 5½-in. by 3½-in. plate. I have never had to reduce this separation for portraits even at 2 ft. away, but for small objects at very close quarters, say 10½ in. from lens, the exaggeration of relief is discernible in the slide. On Mr. Benham's basis of 2½ in. the separation at 10½ in. should be 2 13-32 in., and on my 2½-in. basis should be reduced to 2 3-16 in.

The exaggerated relief resulting from too great a lens separation is always accompanied by a corresponding diminution of the apparent size of the object. This I think is entirely a mental effect. I have an old slide somewhere of the Matterhorn from Zermatt, some seven miles distant, in which the camera has evidently been shifted bodily, I should guess some two or three hundred yards, for the exposures of the two halves. (The nearest foreground object, by the way, is about 300 yds. away.) The effect in the stereoscope is that of looking at a small model on the table under one's nose.

I do not know what limits there are to a trained sight's stereoscopic vision, but I should think it would require a trained vision to decide which was the further away of two vertical rods, one say 1 yd. high at 100 yds. and one 1 1-100 yd. high at 101 yds., viewed from the base level.

It is a long stretch back to my Jules Verne days, but I remember that Capt. Nemo, of the "Nautilus," was described as having eyes very widely set, and, in consequence, powers of stereoscopic vision approached by no other member of the crew of that early submarine.

The few friends I have measured vary no more than 1-16 in. one way or the other from the 2½-in. eye separation. It would be interesting to know what the average adult separation is, also the extreme variations met with.—Yours truly,

R. W. BLAKELEY.

4, Seedley Park Road, near Manchester.

MOUNTING BLOCKS TO POINT MEASURES.

To the Editors.

Gentlemen,—It is unnecessary to notice the first five paragraphs of Th. Eamer's comments of December 5. If he has tried to improve conditions in block mounting he deserves thanks, but to claim for the trade generally that conditions as at present are all that can be desired is claiming too much. It is good news to learn that there is no obstacle in the way to successful mounting to points. But "compressed sawdust" and similar subterfuges which chip away readily are worse than anything.

As there is no method of locking up a forme of type to beat side-sticks and quoins made of wood—Hempel quoins being the nearest in efficiency—so no substitute, so far, equals wood for mounting plates, except when mounted on metal. Where firms cast their own types, stereo and electro plates are often mounted on quotations or quads after the type is imposed in the chase. Parker's patent mounts and patent register-finding are too costly for the smaller single blocks.

This week (not ten years ago) I was given a block to include with some letterpress in a job. The block was new, and when placed in a panel showed that it was mounted crooked, and the mount was wider in one part than another. To remedy this the comp. lifted the plate, running the risk of breakage and battering the design when nailing down again. As a price was given for the job this extra time was all loss. This careless mounting is typical of

the average block-maker to-day, including houses who cater for stock electro'd designs.

Every employer in the printing trade is not a practical man, and first cost in buying plant weighs with him—he cannot, and will not, see the comp.'s view, especially where quads and furniture are wanted: even practical men look askance. One such employer inferred that the point system was a "red herring drawn across the path" of the printer to create more trade for the typefounder. "Luckily" for him his office afterwards was burnt out—to-day his office is strictly on point body.

The printer in search for ideal conditions finds many pitfalls. About 1884, when the point system began to be talked about, a ring foundry offered to cast types on point bodies—but left it to the confiding printer to find out that the system was based upon their own pica, which was larger than the American. In 1900 another ring founder issued a booklet praising the advantages of the old body types over the new innovation. To-day they cast their types on American point body.

After standing out as long as possible, all ring founders now not only cast on point body but on point line and point set. All types, unless otherwise ordered, are supplied on point body, and 10 per cent. extra is charged when old bodies are ordered. In face of these terms, however, some time ago a ring firm supplied a fount of minion Roman types instead of 7-point body, and the error was only discovered by the printer after ordering "sorts" later on. This same firm also supplied a fount of brass type stated to be 18-point, which was not only untrue to each other in body, but varied in height to paper.

By the aid of cast-iron furniture, brass spacing material, and Hempel quoins an attempt has been made to introduce point system in gold-blocking for the binder. Many jobs can now be done from type which other binders find necessary to cast a stereo or electro—binder's height—to execute.

Such are a few of the pitfalls the poor printer finds himself subject to. No wonder he looks shy at innovations.—Yours truly,

J. HURST.

Shaw Heath, Stockport, December 18, 1919.

MINIMUM FLEET STREET PAY FOR PHOTOGRAPHERS.—After much correspondence, several meetings, and the most delicate negotiations, an agreement between the N.P.A. (Newspaper Proprietors' Association) and the N.U.J. (National Union of Journalists) has been arrived at. Although at the moment of writing the agreement has not been signed by both parties, it is expected that the document will have been signed and sealed by the time these lines appear. It relates to all London morning, evening, and Sunday newspapers published by firms who are members of the N.P.A. The agreement is printed in full in the current issue of the Union's organ, "The Journalist," but it is only the clause (No. 12) which deals with photographers that will interest our readers. The minimum weekly rates of payment to be observed by all newspaper proprietors in respect to photographer pressmen and printers from the age of twenty-one, according to the years of service (not necessarily in the same office) are as follow:—Photographer pressmen:—

First and second year (improvers)	£4 4 0
Third and fourth year	5 5 0
Fifth year	6 6 0
Sixth and seventh year	7 7 0
After seventh year	8 8 0

Cases of men who are unfit either through age or incapacity are to be dealt with by a small joint committee. The minimum weekly rates for printers are given as follow:—

First two years as printers	£3 3 0
Third and fourth years	4 4 0
After fourth year	5 5 0

Head printers (of photographs) are to be paid by mutual arrangement from the time of appointment to that position, but in no case less than £5 5s. Another clause (No. 9) deals with hours of work and holidays, which need not be detailed here. Suffice it to say the clause is a particularly good one, and newspaper workers will have no cause to grumble about long working hours and short holidays.

Answers to Correspondents.

SPECIAL NOTICE.

In accordance with our present practice a smaller space will be allotted to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- W. C.—Apparatus for making the living portrait cards is supplied by Move-O-Graphs, Ltd., 60, Doughty Street, London, W.1.
- E. K. P. (Vernon, B.C.).—The makers of the Sanderson camera are Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.
- H. C. E.—If you have natural aptitude, yes. A good teacher of many years experience is Mr. T. S. Bruce, 4, Villas-on-Heath, Vale, Hampstead, N.W.
- C. C. W.—The following are the journals dealing with cinematography:—"Kinematograph and Lantern Weekly," 85-93, Long Acre, London, W.C.2; "Bioscope Operator," 85, Shaftesbury Avenue, W.C.2; "Cinema News," 30, Gerrard Street, W.
- K. W.—We do not know of such a lens. The effect you describe is usually obtained by tilting the copy considerably and using an ordinary lens greatly stopped down for the sake of depth. In this way you can distort a flat original in one or other of its two dimensions.
- M. B.—There are no special materials for while-you-wait photography, the method of which consists in developing and fixing quickly and printing or enlarging from the wet negative. About the best firms for apparatus for this branch of work are Messrs. Fallowfield, 146, Charing Cross Road, London, W.C.2, or Messrs. Billecliff's Camera Works, Richmond Street, Boundary Lane, Manchester.
- L. B.—Registration of trade names is now done at the Patent Office, 25, Southampton Buildings, Chancery Lane, W.C., where you could obtain a circular of instructions for the registration of a trade name. If you mean printers' type, you can buy from such printing supply houses as Messrs. Winston, Shoe Lane, London, E.C. If you mean rubber type, it is supplied by Messrs. E. Richford, 8-9, Snow Hill, London, E.C.1.
- T. and C.—We do not think that too strong a contrast of light and shade will be found if a diffuser be fixed in the front of each lamp, and proper reflectors be used to illuminate the shadow side. When working close to the light a thin gauze head-screen is very useful to further soften the light. Ten 500 c.p. lamps would give the same illumination as five 1,000 c.p. ones, but would cost more for fitting, without, so far as we know, giving any advantage.
- E. G. P.—7½ ins. is much too short a focal length for use with a half-plate condenser. 9 ins. is the shortest focus which should be used, and it is all the better if the focal length is 10 ins. or 12 ins. As regards aperture, this should not be less than $f/8$, and, better, of $f/6$ or $f/4$. With an arc source of light you can get on all right with the smaller apertures, but using a larger light-source and small aperture is liable to give rise to uneven markings on the enlarging easel.
- F. F.—Generally speaking, the focal length for pleasant "drawing" of half-plate portraits should be about 10 ins., but this makes a very big lens for an outdoor half-plate camera, and our advice to you is that you should content yourself with a smaller aperture rather than with a shorter focal length. We think $f/6$ ought to be quite fast enough for out-of-door work in the way of portraits, even in dull weather; it is certainly as rapid as is useful in a lens of this focal length for ordinary subjects.
- A. M.—We are afraid it is difficult to say anything more definite as to the means of avoiding these markings than was said by Mr. Barnes in the article of June 6. Apparently some papers are more liable to give them than others; and a further point is that they

are sometimes avoided by bringing the prints into firm contact with the glass plate whilst both are under water or immersed in the glazing solution. Perhaps one or both of these suggestions may help you to prevent the defect. We wish we could say more, but unfortunately the exact cause of the markings is very imperfectly understood.

- J. W.—A negative image on a dry-plate can be converted into a positive by chemical baths, but with almost every plate it is a very uncertain business owing to the thickness of the emulsion film. We gave a résumé of the working methods in an article in the "B.J." of April 18 of this year, to which we must refer you. If you can do with very slow plates, about lantern-plate speed, you can easily effect reversal by almost any of the processes mentioned in the article by using a special slow process plate of the Wratten Division of the Kodak Company, which has a very thin film something like that of the Autochrome plate.
- J. H.—1. Unless both negative and print are thoroughly dry there is a danger of the paper sticking to the negative, and also causing brownish patches of stain on the negative. 2. We have never tried it, but we do not think it would work. We suggest the only thing to do would be to intensify with chromium and then see what you can do in the way of removing all the intensification with Farmer's reducer, or, better, iodine cyanide. 3. No; the best thing is to keep to a developer of fixed composition and let under and over-exposures take their chance. 4. Many of the usual supply houses; for example, Griffin's, Kemble Street, Kingsway, London, W.C.2. It is a fairly cheap material.
- W. T. S.—Your difficulties are characteristic of the medium. Colours on the best of water-colour paper always dry lighter; the same happens with matt photographic paper. Therefore the artist must build up or allow for the change in single washes. With velvet (gelatine) surface it is usual to rub over with artists' prepared ox-gall to assist the easy flow of water-colours. If a gelatine-collodion velvet paper, it is best to abrade the surface with pumice powder to obtain a "tooth." Any patchiness of working can be hidden by a rub over with wax in turpentine, or two coats evenly applied of methylated finish. The article, "Preparation of Prints for Colouring," which appeared in the "B.J." of August 9 last, will, we think, answer your purpose.

Paget

Professional Plates.

Two Unrivalled Brands for Studio Work.

PROFESSIONAL EXTRA RAPID (400-450 H. & D.)

Exceptional speed, beautiful gradations, extreme freedom from fog, great uniformity.

PROFESSIONAL MEDIUM (200-250 H. & D.)

The same qualities as the extra rapid brand, but about half the speed.

No Studio is complete without one of these Brands.

A trial will be found well worth while.

For those who prefer BACKED plates the Paget "INVISIBLE" backing should be used. This backing is an efficient preventive of halation, and is completely bleached in the developer. Absolutely no trouble or mess.

Manufactured by

The Paget Prize Plate Co., Ltd.,
WATFORD.

The Saalex Studio Camera.

A triumph of modern design and workmanship.

The Saalex Studio Camera meets all the requirements of the modern professional photographer. It embodies all the movements and adjustments necessary to successful professional portraiture and yet has no unnecessary complications. It is made throughout in London and is constructed of selected mahogany attractively finished in the new dull satin polish. Every adjustment is made quickly and conveniently—Focus-

ing Pinions are fitted at the back of the camera on both sides—Ample Rising Front and Vertical and Horizontal Swing with convenient clamping arrangements are also provided. Each camera is supplied with two single repeating slides and a complement of masks and carriers. The Saalex Studio Camera is the acme of convenience and efficiency and is an ornament to any studio.

Post Card Camera, supplied with two slides, each taking three P.C. size plates side by side. 1/2-pl. Camera, supplied with two slides, one taking two P.C. plates side by side and for two panels on a post card, the other is fitted with carriers, P.C., 5 x 4 and 1/2-pl. and for three panels on a post card.

Post Card Camera is made for use with 1/2-pl. slides as 1/2-pl. camera, also

1/1-pl. Camera, supplied with two slides, one for two 1/2-plates side by side, and carriers for all usual sizes are included.

Is Your Studio Complete?

*We specialise in bargains
for professional photographers.*

Your studio is never complete. There is always some little, or perhaps some big thing lacking something that will help you to do better work and thus increase your business. It may be a new lens, a new camera, or some dark-room accessory like an enlarger. You can probably think of something now that you would like to have in your studio. Why not have it? Is it a question of cost? In all probability we have that very article in stock at a price to suit your pocket, and remember everything we sell is guaranteed to be in sound working order. Let us send you our second-hand list; it contains hundreds of bargains for the progressive professional photographer.

FOCAL-PLANE CAMERAS.

1-pl. Nettel Deckrollo Focal-plane, 8½-in. Zeiss Tessar F. 4.5 anastigmat lens, self-capping focal-plane shutter, speeded from 1/10th to 1/2,000th part of sec. and time, focussing adjustment, 4 double dark slides, solid leather case, unsoiled; £32 10s.

1-pl. Professional Model Goerz Anschütz, Goerz Dagor Series III. F. 6.8 double anastigmat lens, focussing mount, focal-plane shutter, speeded from 5 to 1/1,000th sec., direct vision finder, 3 double dark slides, and leather case; £19 15s.

Postcard Lancaster Focal-plane, Goerz Celor F. 4.5 anastigmat lens, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, double extension, rack and pinion focussing, rising front, hooded back focussing screen, 3 dark slides, solid leather case; £14 14s.

Postcard Tropical Model Goerz Anschütz, Goerz Dagor Series III. F. 6.8 double anastigmat lens, focussing mount, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, direct vision finder, hooded back focussing screen, 3 double dark slides, solid leather case, as new; £26 10s.

1-pl. Goerz Anschütz, latest model, Goerz Dagor Series III. F. 6.8 double anastigmat lens, focussing mount, self-capping focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, outside adjustment, direct vision finder, hooded back, focussing screen, 3 double dark slides, solid leather case, absolutely as new; £28 10s.

Postcard Teak Tropical Model Ernemann Focal-plane, Zeiss Tessar F. 6.5 anastigmat lens, in focussing mount, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, Russian leather bellows, direct vision finder, 3 double tropical dark slides, film pack adapter, solid leather case, unsoiled; £22 10s.

5 x 4 Zeiss Minimum Palmos, Zeiss Tessar F. 4.5 anastigmat lens, in focussing mount, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, direct vision finder, 3 double dark slides, leather case; £24.

No. 1. Speed Kodak, Goerz Celor F. 4.8 anastigmat lens, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, long extension, rack and pinion focussing, direct vision finder, daylight loading, for film 4½ x 2½, complete in solid leather case; £16.

5 x 4 Goerz Anschütz, Goerz Dagor F. 6.8 anastigmat lens, focussing mount, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec., direct vision finder, 3 double dark slides, leather case; £11 5s.

1-pl. Goerz Tropical Anschütz, Goerz Dagor lens, F. 6.8, focussing mount, focal-plane shutter, speeded from 5 sec. to 1/1,000th part of sec. and time, direct vision finder, 6 tropical double dark slides, leather case, in finest order; £15 10s.

Lever Press, for perforating proof prints "Rough Proof," complete, in perfect order; £1 15s.

Extra strong Lever Press, for impressing designs on mounts, will take die up to 3-in., and give impression up to 6-in. from edge of mount, perfect order; £1 17s. 6d.

FIELD AND STUDIO CAMERAS.

10 x 8 Square-bellows by Hare, finest Spanish mahogany, double extension, rising and cross front, swing and reversing back, Ross 10 x 8 rapid Symmetrical lens, F. 8, 3 double bookform slides, leather case; £21.

10 x 8 Triple-extension Royal Ruby, compound rack focussing, extensive rising front, swing and reversing back, T.-P. shutter, Dallmeyer 10 x 8 R.R. lens, turntable, 2 double dark slides, and case; £25 17s. 6d.

12 x 10 Square-bellows Professional by Skinner, finest Spanish mahogany, double extension, rising and cross front, swing and reversing back, 12 x 10 Ross rapid Symmetrical lens, 3 double bookform slides; £24.

15 x 12 Square-bellows Ross, Spanish mahogany, double extension, rising and cross front, swing and reversing back, 16-in. Cooke Series V. anastigmat lens, 3 double dark slides, leather case; £39.

1/1-pl. Siebel Studio Camera, extra long extension, compound rack focussing, swing back and side swing, Ross Portrait lens, 4 repeating backs, complete on double pillar ebonised stand, archimedean rack rise and tilt; £26.

15 x 12 Herbst Studio Camera, extra long extension, rack and pinion focussing, swing back, Ross Portrait lens, rack mount, one 15 x 12 roller-curtain slide, 1/1-pl. repeating back, two 1/1-pl. slides, double-pillar studio stand, archimedean screw rise and tilt; £25.

1/1-pl. Salex Studio Camera, very long extension, rack and pinion focussing, rising front, swing back and side swing, Dallmeyer 3B. patent Portrait lens, F. 3, soft focus adjustment, 2 1/1-pl. repeating backs, and carriers; £40.

1/1-pl. Studio Camera by Brooks, double extension, archimedean screw focussing, rising front, swing back, Fallowfield Portrait lens rack mount, 2 double repeating dark slides, one single; £10 5s.

1/1-pl. Spanish Mahogany Studio Camera, 14½-in. Cooke Series II. F. 4.5 Portrait lens, iris mount, soft focus adjustment, extra long extension, rack and pinion focussing, rising front swing back and side swing, 2 1/1-pl. repeating backs, and carriers; £17 17s. 6d.

15 x 12 Middlemiss Field Camera, double extension, rack and pinion focussing, rising front, swing back, It. B. lens, F. 4, 2 double dark slides; £12 10s.

1/1 pl. Banderson Field Camera, extra long extension, Universal rising, falling and swing front, swing and reversing back, 10-in. Voigtlander Collinear F. 7.7 anastigmat lens, iris mount, 2 double bookform dark slides, in finest order; £24 10s.

1-pl. Spanish Mahogany Studio Camera, extra long extension, rack and pinion focussing, rising and falling front, swing back and side swing, Watson quick-acting Portrait lens, F. 4, complete with 2 repeating backs, one to take 2 postcards side by side; £16 10s.

1-pl. Professional Mahogany Enlarger, latest pattern, 8½ in. plano-convex condenser, all-way carrier, with rack revolving, rising and swing movement, extra long extension, compound rack focussing, rising front, special enlarging objective, Russian iron light chamber, with rack adjustment for centring light; £17 2s. 6d.

REFLEX CAMERAS.

1-pl. Ensign Model A Reflex, Goerz Dagor Series III. F. 6.8 anastigmat lens, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, long extension, rack and pinion focussing, reversing back, 3 dark slides; £12 10s.

5 x 4 Goerz Folding Reflex, Goerz Dagor Series III. F. 6.8 double anastigmat lens, focussing mount, latest model self-capping focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, also pneumatic adjustment to five seconds, deep focussing hood, reversing back, 3 double dark slides, leather case; £26.

P.C. Britisher Reflex, Cooke Series II. F. 4.5 anastigmat lens, self-capping focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, long extension, revolving back, 3 double dark slides, film pack adapter, leather case; accept £24 10s.

1-pl. Popular Pressman Reflex, Velos F. 4.5 anastigmat lens, focal-plane shutter, speeded from 1/15th to 1/1,000th part of sec. and time, long extension, rising front, reversing back, deep focussing hood, 6 dark slides and case; £15.

3½ x 2½ Voigtlander Reflex, Busch Omnar F. 4.5 anastigmat lens, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, long extension, revolving back, 3 double dark slides, film pack adapter, leather case; £17 10s.

1-pl. Staley Britisher Reflex, Ross Homocentric lens, F. 6.8, self-capping focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, revolving back, spring-raised mirror, 3 double dark slides, film pack adapter, leather case; £17 10s.

3½ x 2½ All-British Planex Reflex, Ross Homocentric lens, F. 5.6, focal-plane shutter, speeded from 1/10th to 1/1,000th part of sec. and time, rack and pinion focussing, long extension, rising and falling front, revolving back, 6 double dark slides, and case; £16 10s.

1-pl. Marion Soho Reflex, Ross Xpres F. 4.5 anastigmat lens, focal-plane shutter, speeded from 1/16th to 1/800th part of sec. and time, rack and pinion focussing, long extension, revolving back, Mackenzie-Wi-hart slide, 12 envelopes, film pack adapter, solid leather case, in finest order; £32.

1-pl. Ensign de Luxe Reflex, Berthiot F. 5.7 anastigmat lens, self-capping focal-plane shutter, speeded from 1/10th to 1/1,000th part of a second and time, outside adjustment, extra long extension, rack and pinion focussing, revolving back, 3 double dark slides, condition as new; £36.

1-pl. Marion Soho Reflex, 8½-in. F. 4.5 Ross Xpres lens, focal-plane shutter, speeded from 1/16th to 1/800th part of a second and time, long extension, revolving back, 3 double dark slides, film pack adapter, leather case; £52 10s.

Postcard Butcher's Coronet Enlarger, polished oak, chain and sprocket focussing adjustment, 7 in. plano-convex condenser, negative carrier with rack adjustment, Petzval enlarging objective, rack mount, Russian iron light chamber, finest order; £12.

Ordinary Plate.

[Photos. by

Wratten Panchromatic Plates

These two photographs of an antique, lacquer cabinet are examples of simple photography. They are reproduced to show the remarkable value of Wratten Panchromatic Plates compared with ordinary plates. Even in the coarse half-tone reproductions, you can see that the Panchromatic Plate shows all the beautiful colour work which the ordinary plate cannot render at all. It is as easy to use the Wratten Panchromatic Plate as it is to use the ordinary plate—then why not use the Wratten for all your work and secure the better negatives?

LNA LNA

Every day increasing numbers of photographers in all parts of the country are realising the advantages of the L.N.A. Enlargements Service.

They are finding that Enlargements made by the L.N.A. are excellent business bringers. Their fine pictorial qualities are most pleasing to customers. And the customers tell their friends.

Thus the photographer finds that he gets more orders from his existing clients and, by recommendation, gains many new ones who otherwise might have gone elsewhere.

A NEW PHOTOGRAPHIC MORDANT DYE PROCESS. By F. E. Ives	1	DEFENSIA PRACTICA—COLOUR PHOTOGRAPHY: Lipmann or Interference Process	
DOUGLASS TWO-COLOUR CINEMATOGRAPHY	2	of Direct Colour Photography—Pseudo-Colour Processes	3

A NEW PHOTOGRAPHIC MORDANT DYE PROCESS

[A communication from the Hess-Ives Laboratories.]

THE first photographic mordant dye process to attract attention was the silver-iodide process of Dr. Traube (U.S. Pat. 1,093,503, 1914). Metallic silver photographic images converted to silver iodide and immersed in solutions of basic dyes become strongly coloured. If the dye is then fixed by tannin, the silver-iodide can be dissolved out, leaving a transparent dye image. Traube's method was improved upon by Tauleigne and Mazo (U.S. Pat. 1,059,917, 1913) who showed how to produce a silver-iodide image having a stronger affinity for the basic dyes, and, incidentally, that by first hardening the gelatine with alum and then treating the silver-iodide image with a strong solution of potassium iodide, it was made so transparent that for most purposes it was unnecessary to dissolve out the silver-iodide image. The step of hardening the gelatine in alum to prevent it from softening and dissolving in the strong potassium iodide solution was omitted in the U.S. Patent specification, but was published in the "British Journal Photographic Almanac, 1912," page 653. Hoyt Miller (U.S. Pat. 1,214,940, 1917), as a result of experiments with the process without alum hardening, declared the process unworkable, and broadly claimed the production and dyeing of a transparent silver-iodide image, he hardening the gelatine with formalin. I have myself operated the Tauleigne-Mazo process with perfect success.

Incidentally, it had been discovered that silver ferrocyanide, silver chromate and some other silver salts could be similarly dyed, but not with satisfactory results. Fox (U.S. Pat. 1,166,123, 1916) disclosed the fact that a vanadium-toned silver image mordanted basic dyes, and Crabtree and Ives (priority to Crabtree) independently discovered that a copper-toned image had the same property to a very notable and useful degree. The copper-toned image, like the transparent kind of silver-iodide image, is sufficiently transparent for most purposes without "fixing out," but can be made perfectly transparent by fixing in "hypo" without first fixing the dye image with tannin. It has the disadvantage for some purposes that the copper-ferrocyanide image is itself coloured (red-brown), and will not serve as the base for pure blue and green images. It has proved perfectly satisfactory for the production of orange-

red images in combination with a cyanotype print in the same colloid layer in my coloured moving picture process (U.S. Pat. 1,278,668, 1918).

Recently I have discovered a new method of producing mordant-dye photographic images, which I think is superior to any heretofore known. The mordant is a chromium compound, the exact nature of which I have not yet determined, but it is not silver chromate, which is of a deep red colour, while the image which I produce previous to dyeing is of a very pure, though pale, yellow colour. It is produced very simply, quickly and cheaply by bleaching the silver image in a solution of equal parts of potassium ferricyanide and chromic acid, the action of which is analogous to that of potassium iodide in that if the solution is weak the image is not transparent, but if the solution is strong, the image is perfectly transparent and of a pale, though pure, yellow colour. It is necessary to wash out the free chromic acid after bleaching. The pale yellow image thus produced has a much stronger affinity for some of the basic dyes than either silver iodide or copper ferrocyanide. In fact, the silver image, for the best results, must be thin and superficial.

My bleaching solution is made with one ounce each of potassium ferricyanide and chromic acid in one gallon of water, at which strength it acts very quickly and produces a transparent yellow image. Transfer to running water should be made immediately when the image is completely bleached, to avoid over-hardening of the gelatine by the chromic acid. Long washing is necessary to clear out the free chromic acid, but it discharges rapidly in water containing a little soda bicarbonate, and the image also dyes up quicker and clears more rapidly after dyeing if the soda bicarbonate is used. I always use it, but too long immersion whitens the image, reduces its transparency, and produces a weaker, though still strong and brilliant dye image.

A typical dye bath is made by dissolving 10 grains of safranin in 4 ounces of alcohol and adding it to one quart of water made slightly acid with acetic acid. For complete dyeing, an immersion of half an hour or more may be necessary. This will stain the entire film deeply, after which it may be

cleared by washing in water containing a very little acetic acid. Other very active dyes are malachite green and auramine.

The images which have been whitened by long soaking in soda bicarbonate solution have the same appearance and

transparency as silver ferrocyanide images, but have many times more mordanting power—more, even, than silver iodide.

F. E. IVES.

November 11, 1918.

THE PATENTED PROCESS.

In supplement to the above note by Mr. Ives we publish the details of the dye-toning process as set forth in the specification of the patent No. 113,617 granted jointly to him and the Hess-Ives Corporation, in which the process is described as follows:—

The invention may refer to any photographic image, whether negative, positive, or diapositive, and the method of producing the same, whether for the purposes of colour photography, monochrome photography, or motion picture photography.

As an instance of the principles of the invention, the production of a red positive image will be described, and in that connection it may be presupposed that a suitable negative such as the ordinary black or silver haloid negative has been obtained, which, in the case of colour photography, may be one of a set of colour-selection negatives representing, for example, the green elements of the subject.

The method may commence by printing an ordinary black diapositive. Next, this black positive is to be converted into a coloured positive. This is effected by a copper-toning process by which the silver image is converted into a copper-red image, the toned image being further treated to afford a satisfactory and permanent coloured photographic image of the proper depth and hue.

The silver or black positive is first soaked one or more hours in a copper-toning solution made up of the following solutions:—

SOLUTION A.	
Potassium ferricyanide	50 grs.
Potassium citrate	240 grs.
Water	20 ozs.

SOLUTION B.	
Copper sulphate	60 grs.
Potassium citrate	240 grs.
Water	20 ozs.

A mixture of equal parts of Solutions A and B gives the desired toning solution, and when the diapositive has been soaked for the requisite time, it will be found to have been converted into a copper-red coloured image. This image is somewhat degraded by the presence of silver ferrocyanide, and it is, therefore, usually preferred to dissolve out this silver salt by the use of sodium thiosulphate ("hypo").

The copper-toned image thus produced is usually insufficiently deep or bright, or not of the desired hue, for colour photography or other photographic purposes. The inventors have discovered that the copper-toned image is capable of acting as an extremely efficient mordant for basic dyes, and the principle of the invention is the production of the coloured image by a combined copper-toning and mordant-dye process, it being believed to be new to produce a copper-toned image and then utilize the same for the mordanting of suitable dyes so as to strengthen or modify the photographic image to the desired depth and hue. The final image consists of the copper-red image combined with the mordant-dyed image.

In its broader aspect the invention may be carried out by subjecting the copper-toned image having a reddish colour to a bath of any soluble dye capable of being selectively mordanted by the copper image. Not only red but blue or yellow or other dyes might be so employed. Specifically, the case of increasing the depth or brightness of the copper-red image by means of a red dye will now be described, and it is to be understood that the mordant

dyeing step can be carried out at any stage of the complete process, although it is preferred to effect the dyeing after the dissolving out of the silver salt so as to permit the exercise of the judgment by inspection and the stopping of the dyeing process at the most satisfactory point.

Having the copper-red positive free of the silver salt, this may be soaked in the selected dye-bath, for example, an aqueous solution of fuchsine dye containing a small quantity of acetic acid. Owing to the fact that copper is an effective mordant for certain alkali or basic dyes, including the one mentioned, the positive is caused to take up selectively a substantial amount of the fuchsine dye. After this treatment the positive should be washed out in water containing weak acetic acid so as to remove the unmordanted part of the dye from the colloid or gelatine containing the image. When dry, the positive is completed.

The copper-toned and mordant-dyed image of this invention is easy to produce, and is easily controllable during the process, and the image is particularly advantageous for use in connection with multi-colour photography, as no interference is caused with the successful blending of the image with images of other colours, for example, with a cyanotype blue image produced either before or after the mordant dyeing of the present invention.

The present process is very elastic, since the finished print may be tried out in the projection lantern or otherwise, and if it is found that the colour is not exactly as desired, it may be further modified either by adding or subtracting colour almost as readily as in initially carrying out the process. The colour may be enhanced by further mordant dyeing or may be reduced by soaking in acidified water.

In one respect it will be seen that this invention consists in first forming an insoluble or pigment image of material having strong capacity for mordanting and then reinforcing the image by dye-bath treatment, the dye being mordanted selectively so as to strengthen or modify the original image.

The fuchsine dye mentioned will give a purplish red result, whereas an orange red may be obtained by the use of auramine dye, and a mixture of the two or of other dyes may be employed so as to secure the results which are dictated by experience and the character of the subjects. An example of a satisfactory mixed bath is as follows:—

Fuchsine	0.13 gms.
Auramine	0.26 gms.
Water	5,000 c.c.s.
Acetic acid	8 c.c.s.

The dyes may be first dissolved in a little alcohol and then added to the water, and the dyeing process may be continued sufficiently to reach the limit of mordanting action, which may be one or more hours. The unmordanted dye in the gelatine may be subsequently dissolved out by soaking in water preferably made slightly acid.

The mordant dyeing of the copper-red image may be performed either before or after the dissolving out of the silver salt, and sometimes when the silver image is thin, the fixing thereof may be entirely omitted.

Since many matters of order and procedure, particular ingredients and colours, and other features may be variously modified without departing from the underlying principle

DOUGLASS TWO-COLOUR CINEMATOGRAPHY.

Particulars of the process of colour cinematography devised by Mr. L. F. Douglass are given in the extract, printed below, from his patent specification, No. 117,864. As was said in some notes on Mr. Douglass's work some months ago, he is one of the newer experimenters in this field, and we believe that he is now engaged on a process of a different kind.

The invention relates to natural colour cinematograph films formed from a negative series, the images in which have been taken through rotating colour filters, usually red and green alternately. The process includes the masking of one set of alternate positive images with varnish during the subjecting of the other set to the colouring solution, so that there is no possibility

of the colour creeping or passing to the wrong set of images, and the colour is caused to be finally inherent in the emulsion coating of each set of positive images, so that it will not run or creep during washing of the film.

A positive film is first produced wherein every other image possesses a red or yellowish-red colour value and the remaining alternate images a green or green-blue colour value, this film being in black and white. By toning, tinting or dyeing, the red colour value images are then coloured red, and the green colour value images green, the colouring being produced by toning or tinting so that the finished coloured film is a unitary film wherein the colouring is inherent in the film itself, and each set of images (green or red) is masked and protected whilst the other set is being coloured. The images on the positive film are coloured, it will be understood, to correspond with the colour screens employed in taking the negative.

Toning consists in either wholly or partially replacing the silver image of the positive film by some coloured compound, the clear portions or high-lights of the image, consisting of plain gelatine, remaining unaffected and colourless. Tinting on the other hand, consists in immersing the film in a solution of dye which colours the gelatine itself, causing the whole picture on the screen to have a veil of colour over it.

The black and white positive film is coloured or dyed in the following way:—

All the pictures of red value in the film are first masked so as to protect the red colour value images against the action of the green or green-blue colouring solution, while these green or green-blue images are being toned or tinted. As a mask one may employ a suitable good quality dye-proof varnish which can be washed off without affecting the film. A suitable mask would be afforded by photographic varnish, dye-proof and soluble in alcohol.

The most suitable dye-stuffs for tinting are the so-called "acid" dyes which are alkaline—usually sodium salts of organic acids. The dye employed should be inert and not attack the gelatine or support. It should not "bleed" to any considerable extent when the film is washed. It should also be stable to light, and not be dichroic, and not change colour on dilution.

In the practice of the invention, certain desired colours may be obtained by admixture to reproduce any given tint. The dyes employed are standard dyes, for example, as follows:—

Name used in Formula.	Commercial Name
Cine red.....	Chromotrop FB.
„ orange.....	Orange GRX.
„ yellow.....	Quinoline yellow.
„ blue-green.....	Brilliant patent blue
„ blue.....	Naphthamine blue 12B

The above dyes are the commercial grades as supplied by the various dye makers, and contain on an average about 20% of loading material in the form of sodium chloride or sodium sulphate, which is in no way injurious to the film. A green dye that is suitable for this work is what is commercially known as acid green made by Wells and Richardson Co., Burlington, Vt. The proportions of these dyes are as follows:—

1 oz. 5 drams of blue-green dye to 1 oz. of the yellow and 10 gallons of water.

For the red dye I use 3 oz. of dye to 5 gallons of water

For the special blue-green dye, furnished by Wells, Richardson Co. I use 6 oz. of dye to 5 gallons of water.

In all dye baths $\frac{1}{2}$ oz. acetic acid is added to 1 gallon of water.

The time required for dyeing is from $1\frac{1}{2}$ to 5 minutes. When the dye will no longer bring the film to the proper colour in five minutes it is considered exhausted and thrown away. The dye bath in practice is maintained at about 65° F. Since the red value pictures are varnished over or otherwise suitably masked, the green or green-blue dyeing in no way affects them.

The partially dyed film is then rinsed in water to remove any surplus of dye and where varnish is employed as a mask, the film is then immersed in ethyl alcohol of approximately 190° proof to remove the varnish.

After drying are masked all the pictures that have been dyed green, and all the unmasked pictures, taken for red value dyed, with the red dye set out above. The dyed film is again rinsed in water to remove any surplus red dye, the film dried and the masks removed.

If varnish has been used as a mask in the red dyeing operation, the same process is used for removing the varnish from the green coloured pictures as was employed above when removing the varnish from the red colour value pictures. The finished film has alternate pictures of red and green, or red and green-blue, and the film after being dried is ready for exhibition in a moving picture machine as in standard practice.

Although the tinting or dyeing by the method and means above described affects the colouration of the entire body of the gelatine, high-lights as well as the tones and half tones of the images, so that all the green pictures have a veil of green colour over their entirety, and correspondingly all the red pictures have a veil of red colour over their entirety, nevertheless when these pictures are projected on the screen in rapid succession, the green and the red in the high-lights neutralise each other, so that white light is seen on the screen. So far as the results are concerned to the observer, the whites of the projected pictures are apparently formed by directly transmitted white light.

The toning process does not affect the whites in the pictures of this improved cinematographic film; therefore, during projection there are passed only just such colours as are necessary to reproduce the picture in natural colours. Since the whites or high-lights in the images on the black and white positive are not coloured, or at least are less deeply coloured than other portions, the whites of the projected pictures are formed by directly transmitted white light.

As there is no change whatever in the projecting machine, strips of this film can be put in on the same reel with the black and white so part of the reel could be run in black and white, and part of it in colour, if desired.

By colouring the pictures, either by tinting or dyeing, or by toning, so that the colouring is inherent in the emulsion-coating of the film, not only a greater brilliancy, but a better definition and greater sharpness of outline is obtained; and very much less light is required than where any mechanical screens or filters or other mechanical colouring means outside the emulsion itself, are employed.

In this specification and in the claims the word "coloured" is comprehensive of tinting or toning, the result of which is to render the colouring matter inherent in the colour valued emulsion-coating of the film

DECENNIA PRACTICA—COLOUR PHOTOGRAPHY.

Under this heading we apply to the various branches of colour photography the processes of collection and arrangement accorded to some fifty departments of ordinary photography in the "B. J." during 1916. These extracts are from issues of the "British Journal Almanac" of the years 1906 to 1915, and the present series of epitomes thus reassembles and brings together in compact form much useful information, otherwise scattered through nearly a dozen volumes.—Eds. "Colour Photography" Supplement.

LIPPMANN OR INTERFERENCE PROCESS OF DIRECT COLOUR PHOTOGRAPHY.

Lippmann Formula.—Professor Cajal gives the formula he has found best in practising the Lippmann process. A bad sample of gelatine or inferior silver nitrate will cause impure whites or degraded colours. The gelatine sold by Lautenschlager, of Berlin, gives more brilliant results than Drescher's. The formula is as follows:—

Gelatine	62 grs.	4 gms.
Distilled water	$3\frac{1}{2}$ ozs.	100 c.c. v.
Potassium bromide	8.5 grs.	0.55 gms.

In summer the quantity of gelatine may be with advantage increased by 0.5 or 0.7 gms. (7.7 or 10.4 grs.).

The above should be placed in a glass beaker and heated in a water bath, with constant stirring, until the mixture attains a temperature of between 95 and 105 deg. Fahr. Then the sensitizers should be added:—

Cyanine, 1:500 sol.	84 minims	5 c.c.v.
Erythrosine, 1:500 sol.	34 minims	2 c.c.v.
Glycin red, sat. sol. in abs. alc.	135 minims	8 c.c.v.

The glycin red solution must be prepared only about an hour before use, as it rapidly precipitates.

Immediately after the addition of the above the silver nitrate should be added all at once:—

Silver nitrate freshly powdered 11.5 grs. 0.75 gms.

The temperature of the emulsion may now vary between 77 and 105 deg. Fahr., but it is better to adhere to between 85 and 95 deg. Fahr.

If a very fine grain is desired, the emulsion should be gently stirred whilst the silver bromide is being formed; if, on the other hand, a more rapid emulsion is required, it is advisable to mix the emulsion in a bottle and shake it well. The author's experiences have proved that sensitiveness is to a great extent dependent on the physical phenomenon of agitation. The speed of emulsions can thus be made to vary between 1 and 3. It is also possible to increase the speed by digesting the emulsion for half an hour at 105 deg.—“B.J.,” Sept. 13, 1907, p. 691.

Viewing Lippmann Heliochromes.—The Carl Zeiss Works have devised an instrument for viewing Lippmann interference photographs in which the viewing system is simultaneously used for illuminating the plate. The axis of the viewing system is arranged to one side of the photograph, but perpendicular to it. The lens system in this case is used eccentrically. It may consist of a single

plano convex lens cemented to the photograph as a cover glass. The drawing is a diagrammatic plan view of an apparatus for producing a virtual image by a Lippmann photograph to be viewed with one eye. The image b^1 of the entrance pupil b projected by the mirror a is situated at the focal distance of the lens c , and is reproduced from this and from the photograph d , in as far as the picture-film reflects like a plane mirror, at the position of the eye e . The reproducing pencils produce simultaneously a virtual image d^1 of the photograph d behind the hinder surface of the photograph. There are no means provided in this simple example to abolish the catadioptric images of the entrance pupil, the axis of the lens c passing right across the photograph d . The latter is provided only with a plano parallel cover glass d^0 .—Eng. Pat. No. 32, 1907; “B.J.,” May 31, 1907, p. 414.

The Lippmann Process.—Experiments by Herbert E. Ives, recorded in a paper before the American Physical Society, have shown that the non-formation of laminae at a distance from the surface of the film is due to the kind of developer ordinarily used—pyrogallie acid. This is brought out by sections made of the films, which, wetted so as to swell, are examined with the microscope. It is found that the photographic action extends through the thickest

films practicable to flow. By using other developers, such as hydroquinone, even action throughout the film results. If the developed image is then bleached with mercuric chloride a transparent deposit is obtained, and the reflected light consists of a spectrum band of only a few A.U. in width, the purity increasing with the thickness of film.

A substitute for the mercury mirror has been found. Celluloid varnish is flowed on silvered glass; on drying, the celluloid and silver strip off together. This flexible mirror is then laid on a wet Lippmann film and set to dry. Exposure is made as with dry-plates, the celluloid stripped off, and film developed.—“B.J.” Colour Supplement, August 7, 1908, p. 60.

Ives Flexible Mirror.—H. E. Ives has made a series of experiments in order to discover the most favourable conditions (of thickness and grain emulsion, developer, etc.) for the reproduction of (1) pure monochromatic colours, (2) mixed colours, (3) white, and (4) natural scenes. In the course of his experiments he found that what is best for one of these is not best for others, and he further worked out a portable substitute for the mercury mirror, of particular value when using the Lippmann process in the field.

The following are his directions for making the latter: A glass plate is heavily silvered, and then flowed with a thick solution of celluloid in amyl acetate. When this varnish is dry, the plate is placed under water; this slowly works under the coating of celluloid, lifting it from the glass, and bringing with it the silver. This flexible silver mirror is immediately laid, silver surface down, on a wet Lippmann plate, and allowed to dry there, a necessarily somewhat slow process. When dry, the gelatine film has the silver surface in optical contact with it. The plate may then be exposed at any time in an ordinary plate-holder. After exposure, the celluloid film is stripped from the gelatine, taking with it most of the silver, the plate developed, and, after thorough washing, the remains of the silver removed with a tuft of wet cotton.

This substitute works perfectly for all types of colours, and, except in the laboratory, where a convenient dark-room makes the use of the mercury mirror simple, facilitates the practical working of the process.

A difficulty which has proved rather troublesome is that some of the best sensitizers are apt to lose their effect during the slow drying. Erythrosin acts perfectly; pinacyanol and pinaverdol are apt to fail. This can probably be overcome, either by different choice of sensitizers, by so treating these that slow drying does no harm, or perhaps by finding some more porous substance than celluloid, which acting the same in other respects, will permit of quick drying. Collodion has been tried, but has not been found to strip off the gelatine well.—“B.J.” (from “Astro-Physical Journal”), Dec. 11, p. 942; Dec. 18, p. 965; Dec. 25, p. 979, 1908.

The Lippmann Process in Practice.—In a brochure issued by Messrs. Carl Zeiss, Jena, full details are given for the working of the Lippmann process by the methods and with the apparatus worked out by Dr. H. Lehmann, of the Carl Zeiss works. The apparatus includes a special form of mercury dark-slide and viewing and projecting instruments.—“B.J.” Colour Supplement, Nov. 4, p. 83, and Dec. 2, p. 92, 1910.

PSEUDO-COLOUR PROCESSES.

“Mars-Star” Process.—Captain Lascelles-Davidson and Friese Greene have devised this so-called process in which a bromide print is bleached, and, after rinsing treated all over with a series of colour washes, which act selectively upon the print. The inventors state that the densities (representing colour in monochrome) should be as nearly as possible as follows:—

- White in the original scene should be opaque in the negative.
- Blue should be semi-opaque.
- Green should be of middle density.
- Yellow should be of middle density.
- Red should be of faint density.
- Black should be of clear glass.

If the red developing compound is applied first only the red and yellow deposits in the print will be affected, and will develop up to a red. The blues and greens will not develop up until a de-

veloping compound for such colour is applied to the print, when the colour will be gradually re-developed and built up in the deposit of the print. The highest lights (whites) do not take any colours, and wash quite clean, unless the redevelopment has been carried on too far. It is only during the period of redevelopment that a bromide print shows power to select or repel a colour or colours, after which it becomes stained and untrue; but the latitude allowable in procedure before this stage is arrived at is very great.—“Penrose’s Pictorial Annual,” 1905-6, p. 85; “B.J.,” Dec. 29, 1905, p. 1030

“Solgram” Colour Prints.—This alleged novel process of colour-photography, due to a Mr. W. C. South, of Downington, Pa., U.S.A., is severely criticised in “B.J.,” February 2, 1906, p. 88. It appears to be nothing more than the superposition of gum-prints on a ferro-prussiate image.

A COMPOSITE COLOUR PROCESS	5	DECENNIA PRACTICA COLOUR PHOTOGRAPHY:—	
AN IMBIBITION SCREEN-PLATE COLOUR PROCESS	8	Colour Separation by Dispersion and Diffraction.....	7

A COMPOSITE COLOUR PROCESS.

[The following is the description, from the published specification, of a process for which patent protection in this country is granted to Mr. F. E. Ives and the Hens-Ives Corporation. It will be seen that the basis of it is the combination of a two-colour mosaic screen-plate and a single-plate sensitive to the other of the three primary colour-sensitives. Thus the screen-plate will record the green and blue-violet and the other plate the red. These two materials are arranged with their sensitive surfaces substantially in contact and exposure in the camera made through the mosaic plate. On development two negatives are obtained of the subject, one recording in the two sets of units of its mosaic the green and blue colour-sensations, and the other, over its whole area, representing the red colour-sensation. From this latter negative a blue-green positive is printed. From the two-colour composite negatives pink and yellow positives are printed, the former by green light and the latter by blue light. They may be made successively on a single sensitive surface or separately on two surfaces. The two or three positives—they are preferably dyed gelatine reliefs—are united to form the three-colour print. The specification No. 112,769 enters upon a percentage comparison of the results with those by other processes, but is not clear enough in its language for us to follow it.—EDS., "Colour Photography" Supplement.]

This invention involves a system of colour photography which is novel both in its entirety and in its parts. The primaries may be conveniently designated as, first, blue; second, green; and third, red. The invention is characterised in that all three primaries are represented on two separate negatives produced by exposure and development of two sensitive films. This novel principle results by reason of one of the negatives being composite, that is, produced by exposure through a colour selective screen of mosaic or other pattern, and representing two of the primary colours, while the third primary colour is represented on the other negative, which is in some way rendered insensitive to or is protected from the first two primaries.

This invention is contrary and superior to the well-known three-colour mosaic system, such as that of Lumière, wherein all three primaries share the area of a single negative, and in consequence thereof are all insufficiently represented, especially red, the weakest colour. In the preferred embodiment of the present invention both of the stronger colours, blue and green, share the composite negative, and the weakest image is represented by an entire negative or 100 per cent. of the area. Moreover, where the positives are produced by a bichromated gelatine system, the three-colour mosaic system cannot be employed on account of the impossibility of printing the red-representing positive, since the bichromated gelatine is insensitive to red.

This invention is contrary and superior to the well-known system wherein three separate negatives, representing respectively the three primaries, are made by exposure of three separate sensitive members. That system, unless the exposures are made successively, or a special camera is used, requires

the three sensitive members to be so assembled that the middle one separates the others. This destroys proper focus and sharpness of image, and makes the assemblage rather thick for use in an ordinary camera, and, moreover, the handling of three negatives is inconvenient.

The present system includes a novel sensitive assemblage. A two-colour selective screen or layer is preferably embodied with one of the sensitive members, so as to become a part of the resulting negative. This sensitive member is placed face to face with the second sensitive member with an extremely thin colour screen located between them or on the surface of one of the said members, and exposure is made with the composite colour screen at the front; the thin colour screen may be formed by flooding over one of the members a dye solution which would be allowed to dry thereon, and afterwards be washed out during the subsequent developing processes, the said screen being too thin to affect any material separation of the members. The resulting composite negative is reversed, which is an advantage in assembling the final print.

The present system includes also the novel mode of exposure wherein the light-rays pass first through the composite screen, so as to affect one sensitive layer in pattern and the other layer without pattern. The screen may have magenta-coloured areas for the blue-selection and yellow-coloured areas for the green-selection, the first sensitive layer being insensitive to red. These areas admit the red rays, which pass to the second sensitive member.

The present system includes also the novel procedure from the negatives by printing twice from the composite negative, preferably by light of two different colours (although a similar result is obtainable by having the sensitive print members of

two different sensitivities), so as to secure two positives to be blended with a third positive from the second negative. The novel picture or product is also superior, stronger in colour than the three-colour mosaic pictures of Lumière, and sharper than the pictures made from three separate negatives, and, when produced by the preferred embodiment of the invention, it consists of two patterned monochrome images blended with one unpatterned monochrome image, all of secondary colour.

The invention may be carried out in many ways, of which the one shown in the drawings is the preferred embodiment, and is given for illustration merely as a convenient example. The drawings are all greatly exaggerated.

In these drawings Fig. 1 shows two sensitive members, either

Fig. 8.

rigid plates or flexible films, opened out flatwise. Fig. 2 shows them folded together into face contact. Fig. 3 diagrammatically shows the preferred arrangement and the passage of the light-rays. Figs. 4 to 8 show in side view one mode of making a colour photograph from the negatives produced by exposing the members of Fig. 1 to 3. Fig. 4 indicates printing from the plain negative a positive of secondary colour. Fig. 5 indicates printing from the composite negative by selected light, and Fig. 6 printing from the same negative by different light. Fig. 7 shows one convenient mode of blending the three positives—namely, by superposition, and Fig. 8 indicates these permanently united.

The pair or set of sensitive plates constitute a pack 10, comprising the rear member 11 and the front member 12. They may be secured by strip 13 at the edge, and are thus easily handled and permit exposure in an ordinary plateholder.

The sensitive member 11, which is to provide a negative representing the primary colour red, is preferably the rear member. It consists of a transparent carrier 14, preferably glass coated with a layer 15 sensitive to red. The layer 15 may be thoroughly insensitive to blue light and to green light, in which case practically all the light passing through the front member

12 may pass to it. It is safer, however, to exclude blue light, and even green, and, unless the layer 15 is insensitive to these colours, it should be protected by a screen or coating, or should be stained red. For illustration, a thin red screen 15^a is indicated in Fig. 3.

It is preferred that the front sensitive member 12 be the one to afford the composite or mosaic negative. This faces rearwardly, and comprises, first, the layer 17 sensitive to both blue and green. In front of this is the composite screen 18, supported on a transparent carrier 19, preferably glass. A thin varnish coating 18^a protects the colour pattern when applying the sensitive emulsion 17 over the screen.

By constructing the layer 18 of a microscopic pattern of magenta and yellow, it will pass blue light and green light respectively, according to the pattern, for affecting the front sensitive layer 17. The red rays, to which the front member is insensitive, pass through both the magenta and the yellow areas, and therefore affect the rear member 11 over its whole surface.

The member 12 may be made by coating the glass 19 with fine-grained gelatine, and then printing the desired pattern by a greasy ink. This may be of carmine or magenta colour. By then immersing in a yellow dye, the unprinted portions absorb the yellow colour, giving the desired composite screen. The yellow portions 20 are alternated with the magenta portions 21. This should be coated with amylo-acetate collodion varnish 18^a before applying the blue-green-sensitive emulsion 17.

Fig. 3 shows the red rays passing through the magenta and the yellow units and through the red layer 15^a to the rear member 11. The red screen is shown as cutting off the green and blue rays. The topmost green ray is shown passing through a yellow unit, so as to affect the sensitive layer 17. Yellow is secondary and admits both red and green, but excludes blue. The next green ray meeting the magenta unit is shut off. The first blue ray meeting the yellow unit is shut off. The second blue ray passes through the magenta unit and affects the sensitive layer 17. Magenta is a secondary colour and admits both red and blue, but excludes green. It may be tinged with yellow, so as to soften the effect of the blue light, which is far stronger than the green. This equalisation might be otherwise obtained, namely, by a yellow screen at the lens.

On development of the members 11 and 12, two negatives are obtained. The member 11 gives a plain or unpatterned negative 22, shown in Fig. 4, which represents the red element of the picture. The member 12 develops into a composite negative 23, shown in Figs. 5 and 6. The composite screen 18, being a permanent part, is contained in this negative. The image of the exposed and developed parts of the negative is black and represents the green and blue elements of the picture respectively. Beneath are the magenta and yellow units.

In Fig. 4 a positive 24 is printed from negative 22. This, according to the theory of subtractive colour photography has a blue-green image, and may be, for example, a ferrocyanide print. This colour is the complementary of red. From the composite negatives magenta and yellow positives are obtained. Fig. 5 shows printing the magenta positive from the negative 23 by green light. A green glass 25 is placed above. The image of the print 26 is to be made magenta in a suitable way. Similarly in Fig. 6 a blue glass 27 serves to give the positive 28, the image of which should be the complementary colour yellow.

These successive monochromes could be made successively on the same base, or made separately, as indicated, and afterwards combined. Thus, the positives 24, 26, 28, are shown superposed in Fig. 7, giving an assemblage 29, in which the original picture is reproduced. These may be permanently and intimately united, as in Fig. 8, to form the final product 30. The sensitive member 12 facing rearwardly gives a reversed negative 23,

so that the positives 26 and 28 are reversed. This is an advantage, as it enables one to face them downwardly, as in Fig. 7, upon the upwardly facing blue-green positive 24, which is unreversed.

The three positives 24, 26, 28, may be gelatine reliefs produced by the bichromate process; white light being used to print from the negative 22. The colour may consist of dye absorbed by the reliefs, and the three images could be transferred by imbibition to a single gelatine layer to give the final picture. The pattern or mosaic may be readily made to disappear by minute diffusion of the light or of the dye.

As before stated the foregoing description is that of the preferred embodiment of the invention; the manner of carrying the invention into practice is, however, capable of being considerably modified, and although some of these modifications, as hereinafter explained, may be responsible for different or less satisfactory results, nevertheless, they are all held to fall within the scope of the invention.

It has already been herein demonstrated that with a composite screen comprising only magenta and yellow areas the red or weakest image is represented by an entire negative or 100 per cent. of the area, and from that it will be appreciated that, when the total magenta area bears a certain definite proportion to the total yellow area, the resultant negative will be representative of 50 per cent. blue and 50 per cent. green, so that in all a total of say 200 per cent. will be obtained.

Any variation of the relative totals of the magenta and yellow areas of the composite screen will disturb only the balance of the blue and green in the resultant negative without in any way varying the 100 per cent. red negative and from this it will be seen that by giving effect to any such variation the green can be made to preponderate over the blue or vice versa in the finished product, thus affording considerable latitude in the artistic treatment of different subjects.

The foregoing description has been confined to examples in which the two areas of the composite or mosaic screen are both of secondary colour which is the only way of obtaining 100 per cent. representation of the red or weakest image, it is, however,

possible, in accordance with the present invention for one of these areas to be of primary colour. Such an arrangement would secure results which, although less satisfactory than that just stated, would nevertheless be superior to those attained by hitherto known processes, inasmuch as equality for the three primary colours, say 50 per cent. of each, would be obtained, but in this case the red itself would be of mosaic pattern, that is to say in distinct areas alternating with black or clear areas.

To state a concrete example of the last-mentioned modification, it is assumed that the composite screen comprises alternating areas of magenta (secondary), and green (primary). With such a screen the magenta areas pass blue rays which affect the rear member 11 over only such areas as correspond with the said magenta areas, while the green areas pass only the green rays which affect the front sensitive layer 17, but have no effect on the rear member 11. The consequential result is that after development, the red representing negative 11, will have a mosaic pattern of red representing areas alternating with blank or clear areas, the total result being to secure 50 per cent. blue, 50 per cent. green, and 50 per cent. red.

The original yellow areas 20 might be retained, and the magenta areas replaced by blue, in which case the result would be substantially the same as in that of the last cited example. It would then, however, be possible to vary the size of the respective colour areas, for example, they might be in the proportion yellow areas 60 per cent., blue areas 40 per cent., which would give final totals of colour representation as follows: blue 40 per cent., green 60 per cent., red 60 per cent.

With the before-mentioned three-colour mosaic system of Lumiere the best results that can be obtained are 100 per cent., and, assuming the starch grains to be equally distributed, there is 33½ per cent. blue, 33½ per cent. green, 33½ per cent. red, and any increase of one must be at the sacrifice of the others.

It is well known that red and green are both far less actinic than blue, so that even with the blue 40 per cent., green 60 per cent., and red 60 per cent. previously mentioned, this is far better than has been hitherto possible from the best previously known process.

DECENNIA PRACTICA—COLOUR PHOTOGRAPHY.

COLOUR SEPARATION BY DISPERSION AND DIFFRACTION.

Colour Photography without Filters.—The Drac method briefly described in "B.J.A.," 1906, p. 853, was demonstrated privately in London during February and March, 1906. The apparatus (Eng. Pat. No. 1,008, 1904) provides for the dissection of the spectrum, permitting of the adjustment of the composition and strength of each section to the sensitiveness of the plate so as to obtain the same time of exposure for all three negatives. The apparatus is employed both for the making of the colour-sensation negatives and for the viewing or projection of colour records by additive synthesis. For the latter purpose the positive transparency from the triple negative is placed in the position occupied by the plate, and thus a system of direct colour photography is available in which no coloured means of any kind are used.—"B.J.," Feb. 2, 1906, p. 87.

A later patent of Drac's (Eng. Pat. No. 9,449, 1905) describes modifications in the system of prisms whereby fewer glasses are needed. Drawings, etc., are given in "B.J.," Feb. 9, 1906, p. 111.

Herbert E. Ives (son of F. E. Ives), in examination of the Wood diffraction process ("B.J.A.," 1900, p. 830; and 1901, p. 829), finds that it is erratic, in consequence of the fact that the three gratings, when superimposed, do not act as separate gratings. A new compound grating is formed by two of the replicas getting in and out of step with each other, and this new grating forms a spectrum of its own. In order to avoid the disturbing effects of superimposition, Ives arranges the gratings in strips, applying the principle of Joly's process to the diffraction method. The improved plan is as follows:

In Fig. 1, A is the bichromated gelatine plate rigidly fixed in position; B is a glass diffraction grating; C is a line screen, ruled with at least two hundred lines to the inch, with the opaque lines twice

the width of the transparent; and D a lens, and E a positive colour-record to be copied. The latter is an ordinary set of three positives containing no lines or structure, and the grating is an ordinary continuously-ruled one. With, say, the red record at E, and the corresponding grating at B, an exposure is made, resulting in a series of narrow strips. A second positive is then placed at E, the corresponding grating at B, and the ruling C moved the width of a transparent portion. A second exposure is then made, the opaque lines shielding the previously exposed surface, and a similar treatment given to the third positive. There results finally a picture made up of alternating strips of three different gratings.

To eliminate the grating effects of the narrow strips of gratings considered as lines, the device is used of making the strips (Joly lines) run at right angles to the diffraction grating lines, so that the spectra produced by them are thrown off in another direction and do not enter the eye.

Fig. 2 gives an idea of the appearance of the finished picture under the microscope. The short, fine lines are the diffraction grating lines furnishing the three primary colours; 2,400 to the inch for the red, 3,000 for the green, and 3,600 for the blue.

When viewed with a lens and bright source of light the pictures made in this way are entirely free from the formerly-obtained defects. The colours are pure and brilliant, and, unlike ordinary Joly pictures, the colour-lines are too fine to be visible. The results, indeed, approach those obtained with the Kromskop.

As a further modification of the original method the writer has found it possible to dispense with three gratings and obtain the colours with a single grating spacing properly used. To do this the source of light must be a rather long slit. Viewed through a

grating the slit, of course, gives long spectra parallel to its length. If now the grating be rotated about the perpendicular dropped from it to the slit, the spectra move in toward the slit. [The accompanying shift parallel to the length of the slit is compensated for by the slit being long.] So, by suitable rotation, any desired spectrum

Fig. 1

Fig. 2

Fig. 3.

colour may be obtained at a chosen point. Starting with a grating of 3,600 lines to the inch to give the blue when parallel to the slit, a rotation of about $21\frac{1}{2}$ degrees will give the green, of 42 degrees the red. In the absence of suitable dividing engines to rule three properly-proportioned gratings this affords an exact and easy method of securing the three colours. It has the fourth advantage, that in printing copies such difficulties as securing perfect printing contact will affect all three colours alike, which is not the case with gratings of different degrees of fineness.

AN IMBIBITION SCREEN-PLATE COLOUR PROCESS.

A RECENT patent specification, No. 121,776, of Hans Pedersen, describes a method of making colour prints by a process which combines within itself certain details familiar in other processes.

In reciting the known state of the art in the field of his invention the patentee points out that it has been proposed to produce from a colour diapositive—i.e., a three-colour original positive, for example, an Autochrome plate, another similarly coloured positive view or picture on paper, by using the same method that has proved so successful with plates—that is to say, to expose a sensitized bromide film beneath a positive, comprising a screen of primary colours, to develop and then reverse and fix it. However, to enable the light to reach the eye from such a picture so as to reveal the colours, the light would have to pass twice through the screen or filter, and would thereby be weakened so far as to render the picture seen by the eye, to be lacking in contrast, thus making this method impracticable.

He also points out that, by another known method, a positive reproduction can be had direct from a multi-colour dia-positive by first producing a print therefrom on pigment paper coated with a white pigment and transferring the pigment image on to a black paper backing, then placing a coloured layer in correct register on the pigment coating and allowing the picture to imbibe colours, so that there is obtained a positive picture with correct distribution of light and shade.

According to the improved method the required colours are imbibed from a multi-coloured substratum layer or screen, and for this purpose a transparent base is covered with a screen of not too small meshes and of waterproof colours, which are only soluble in alcohol, for example. Directly on this filter is placed a sufficiently thick gelatine-silver colour-sensitive film, having white pigment incorporated in it. The subsequently mentioned separate treatments

Fig. 3 shows a portion of a picture made in this way with one grating spacing.

Mr. F. E. Ives has devised the following instrument for viewing the pictures:—

Fig. 4 gives the instrument in section. A, B, C, D are the four slits; M a mirror; L_1 and L_2 lenses; P the diffraction picture; and S the slit through which the picture is observed. The lenses, of course, form an image of each slit at A' , B' , C' , D' ; from each of these images, however, a certain amount of light is diffracted by the

Fig. 4.

picture P; from B and C first order spectra fall on S, from A and D, second order. The use of second as well as first order spectra is a distinct advantage in that, as gratings never give a perfectly uniform distribution of light and colour, certain desirable qualities of the picture are found in one order and not in the other, while if both orders are used the resultant evening up of qualities produces particularly satisfactory results.

By disposing the grating lines in a horizontal direction and using horizontal slits as sources, the pictures may be viewed by both eyes, a desirable condition for convenience and comfort. To use, it is merely placed before a window or Welsbach light and the pictures dropped to place.—“B.J.” (from “Journal of Franklin Institute”), Aug. 3, 1906, p. 609.

are based on well-known general treatments or methods, to which reference only is needed here.

An exposure is made beneath a multi-coloured dia-positive or in a camera, as in taking ordinary exposures from the rear through the screen. The image is then developed in non-tanning developer and fixed. The silver deposit is bleached in one of the known bleaching agents which differentially tan the developed parts in accordance with the silver deposit, and is then fixed so as to remove the newly-formed bromide or chromate of silver. The gelatine which has remained soluble is now dissolved in a warm-water bath similarly as is done in the well-known “carbon” process. The remaining white pigment is thus distributed correspondingly to the distribution required in the colour screen picture. On a red spot, for example, only the red parts of the screen are covered with pigment, the others lie free. At a black part the whole screen is free, while at the white parts all the screen is covered. The thickness of the pigment layer corresponds everywhere with the amount of light received by the sensitized film.

After this the pigment layer is pressed on to an alcohol-soaked colourless gelatine layer. The alcohol penetrates through the pigment and causes the colours of the screen to dissolve and penetrate into the white pigment. The colours not covered by pigment pass into and are wholly absorbed by the firmly-pressed-on gelatine layer. When the colours have been sufficiently absorbed by the pigment the two layers or films are separated from each other. For interrupting the colouring action the solvent in the pigment is made to quickly evaporate by means of a warm air current. The white pigment has now been changed to a coloured picture with the correct scale of density according to the different thickness of the layer. By double transfer the withdrawal of the pigment from the screen and its application to a black paper backing is effected. This method is equally suitable for copying, enlarging, and for directly taking photographic views.

COLOUR TRANSPARENCIES FROM COLOUR-SENSATION NEGATIVES.

[A method of printing from colour-sensation negatives which appears designed for the production of complete colour-cinematograph film pictures is described in a recent patent specification assigned by F. E. Ives to the Hess-Ives Corporation, Philadelphia. It consists essentially in producing a multi-coloured picture by forming a composite of (1) a positive from a colour-sensation negative and (2) a positive printed from a positive or negative from a second colour-sensation negative and impressed on (1). Inasmuch as details of such processes are appropriately recorded in these pages we have transferred them from their customary place in the "Patent News."—Eds. "Colour Photography" Supplement.]

This invention relates to the art of colour photography, and has more particularly to do with the process involved in the making of a multi-colour photograph compounded of blended monochrome images of which one or more are printed directly upon a pre-formed colour image. In its complete aspect the process may be said to commence with a set of colour-selection negatives, whether of the two-colour or three-colour system, or other system, which negatives are producible by well-known methods; and the invention provides a novel and advantageous mode of proceeding from such negatives to secure the multi-colour positives or pictures. In one aspect the invention may be said to be directed more particularly to the subject of motion pictures in colour, in which, on account of the minute size of the images, it has been found difficult to secure or ensure exact registration of the component images. The invention, by overcoming such difficulties, prevents the incidental formation of fringes of colour in the making and exhibiting of colour motion pictures.

For convenience the invention is described as applied to the two-colour system, wherein red and green respectively may be considered as the selected primary colours, and blue-green and red respectively the corresponding secondary or complementary colours. While the invention is applicable to many systems wherein the monochrome components of the positive image are produced successively, the later one being produced directly upon and in registry, so as to blend, with the earlier one, it is, for convenience, described as an improvement of the known process in which, after obtaining the negatives representing the selected primaries, which may be respectively referred to as the red-representing negative and the green-representing negative, a monochrome positive is made from one of the negatives. Specifically a blue-green positive is produced directly from the red-representing nega-

tive, this coloured positive being carried in a gelatine film on a suitable support. The green-representing negative, or a diapositive therefrom, is then used to print a red image directly upon the blue-green monochrome print, in registry with the blue-green image. This is preferably done by bichromate sensitising of the gelatine film containing the blue-green image, and then exposing beneath a diapositive from the green-representing negative and thereafter dyeing the exposed colloid by suitable red dye which is selectively imbibed, forming an image blending with the blue-green image and yielding the desired multi-colour print. It will be understood that the negatives and the green-representing diapositive referred to are the usual black, or rather black and clear, negatives or diapositives. To avoid confusion the word colour or coloured throughout this specification is used in a sense distinguished from black or clear.

In practising the before-mentioned known process much difficulty has been experienced in securing accurate registration of the black green-representing diapositive over the previously formed blue-green monochrome positive. Practically speaking, visual registration is necessary, at least in the first instance, and it is found that the most minute visual examination, however carefully made, has not availed to ensure exact registration. The difficulty is enhanced in the case of cinematographic films where the details of the pictures are substantially microscopic, and where, moreover, the slightest inaccuracy in registration is immensely magnified in projecting the picture upon the screen. Inaccuracy in registry means that one or other of the colour images, the blue-green or the red, will overlap at various points, thus producing bright colour fringes in the projected picture, which is extremely objectionable.

The objects of the present invention are generally to overcome the various defects above mentioned, and particularly to over-

come the difficulty in obtaining exact registration in the printing of a second monochrome image over a pre-formed positive print of another colour. Other objects and advantages are explained in the following description or will be apparent to those skilled in the art.

In one aspect the present invention particularly consists in the process of making a blended picture after having secured a pre-formed colour print or positive, by photographically printing a differently coloured image in registry upon, so as to blend with the pre-formed colour print by effecting a photographic exposure through a diapositive, or in some cases a negative, which, contrary to the usual black and clear diapositive or negative, is of a colour which effectively contrasts with that of the pre-formed print, so that the eye is easily enabled to effect exact registration before exposing to light to print the second image. By these means the hitherto experienced difficulty arising out of the fact that the black and clear diapositive affords insufficient contrast with the pre-formed monochrome image during the step of registry, is thus overcome. More specifically, after securing the first colour image, it is preferred to use for printing of the succeeding one a diapositive of the complementary colour, so that during registry the observer practically has before him the final multi-colour or blended image. Specifically, after securing the blue-green positive in gelatine and re-sensitising, a red diapositive secured from the green-representing negative is employed, and with this red diapositive registration above the blue-green image is easily and satisfactorily made prior to the actual exposure and subsequent selective dyeing of the gelatine.

In order to afford a full and complete disclosure of the present invention and the mode of practising it, one practicable mode of procedure and details will now be described step by step.

In the accompanying drawings illustrative of one application of the present invention fig. 1 in side elevation indicates a red-

Fig. 1.

selection negative, fig. 2 a green-selection negative, and fig. 3 a diapositive from the green-selection negative. Fig. 4 indicates the step of printing a blue-green positive from the red-selection negative, fig. 5 the step of printing a red image from the fig. 3

Fig. 2.

diapositive in registry upon the blue-green image, and fig. 6 on an enlarged scale shows the nature of the resulting print. Fig. 7 shows a modification.

Commencing the description of the invention at that point where the colour selection negatives have been obtained, and assuming that one of these (fig. 1) represents red and the other (fig. 2) green, these being the selected primaries, the subsequent procedure may be described as follows:—

Before producing a blue-green positive from the red selection negative, 10, it will be convenient to first secure the red diapositive from the green-representing negative, 11, for the purpose of using such diapositive in exposing and printing the second of the two monochrome images to be blended.

From the black negative, 11, which represents green, a black diapositive, 12, is printed, which may be done in a well-known manner, for example, by merely exposing a silver haloid sensitive plate or film beneath the negative, and developing in the usual way. The black diapositive is next converted into a red diapositive, and the procedure for this may be as follows:—

The diapositive is first soaked over night in a copper toning

solution made up of the following solutions, which can be kept in stock:—

A—Potassium ferricyanide	50 grains.
Potassium citrate	240 grains.
Water	20 ounces.
B—Copper sulphate	60 grains.
Potassium citrate	240 grains.
Water	20 ounces.

A mixture of equal parts of solutions A and B gives the desired toning solution, and, when the diapositive has been soaked for the requisite time it will be found to have been converted into a copper red coloured image. This image is somewhat degraded by the presence of silver ferrocyanide, and it is therefore preferred to dissolve out this silver salt by the use of sodium thiosulphate ("hypo").

It is preferred that the diapositive, 12, should be of a deeper and brighter red than the copper red so produced, in order to

Fig. 3.

give a more emphatic contrast when registering with the blue-green image, and this result may be accomplished as follows:—

The copper red diapositive may be soaked in an aqueous solution of fuchsine dye containing a small quantity of acetic acid. Owing to the fact that copper is a mordant for certain alkali dyes, including the one mentioned, the diapositive is caused to

Fig. 4.

take up selectively a substantial amount of the dye. After this treatment the diapositive should be washed out in water containing weak acetic acid, so as to remove the unmordanted part of the dye. The red diapositive, 12, when dry is ready for

Fig. 5.

printing purposes, and it will be understood that it is a green-representing diapositive, coloured red to contrast vividly with the blue-green monochrome.

The subsequent procedure has already been referred to. The red-representing negative, 10, will first be utilised to secure a blue-green positive image, which may be done by a known silver conversion system, or by any other convenient system. This step is indicated in fig. 4, in which, beneath the negative, 10, is seen the print member, 13, comprising the sensitive layer, 14, over the carrier or glass, 15.

Having the blue-green positive image, the second image may be produced in different ways. One well-known procedure would be to first coat the blue-green image with a protective coating of varnish, 16, as indicated in fig. 7, and apply over that a sensitive layer, 17, before proceeding to expose and print for the red image. Or, as is already known, the blue-green image may be contained in a gelatine layer, 14 (see fig. 5), which may now be sensitised with potassium bichromate. This re-sensitised monochrome may now be exposed beneath the green-representing red-coloured diapositive, 12. This, as previously explained, is easily and accurately performed by reason of the colour contrast between the red diapositive and the blue-green positive image. Following this it is merely necessary to wash out the unaffected bichromate, and immerse for one or two minutes in an acid solution of sodium salt of di-sulphonaphthaleneazo-B-naphthol disulphonic acid, known as fast red or similar dye. By this procedure the red image will be created

by selective absorption, and will be found to be accurately registered with the blue-green image, and therefore properly blended, so that, when magnified by projection on a motion picture screen, the objectionable colour fringes will be substantially non-existent.

In enlarged cross-section the final picture may be somewhat as indicated in fig. 6, wherein above the transparent carrier, 15,

Fig. 6.

the layer, 14, of colloid is shown as having embodied in it the blue-green image, 18, and the subsequently formed red image, 19, the lower part of the colloid layer being clear, as shown at 20.

In cases where it is desired to use a coloured negative as the printing member for the second image, instead of the coloured

Fig. 7.

diapositive, the original black negative may be suitably converted to a red colour, for example, in the manner above described, and in this case a different mode of selectively producing the second image will have to be adopted, for example, the use of a dye like eosine, which is mordanted by the chromium compound produced in the film by exposure to light, but can be washed out of the unhardened portions, thus producing a red positive image by printing under a negative image.

The particular colours mentioned are only instances, and they may be reversed or suitably altered according to the system of primaries and secondaries that may be selected. In the particular two-colour system referred to, the red image may be of various shades of red as circumstances may dictate, and the blue-green image may vary from blue to green, and may, therefore, be referred to as a blue-to-green image.

Other methods than the one given may be employed for con-

verting a black silver image to a coloured image, as required for this process, for example, that already known wherein the silver image is converted to silver iodide and subsequently dyed with an alkali dye which is mordanted by silver iodide; and a silver image converted to silver ferrocyanide will dye selectively with alkali dyes in the same manner. The copper red image is preferable for the object of the present invention because of its intrinsic colour and superior opacity to actinic light, and the greater permanency to light of alkali dyes in combination with the copper mordant.

The claims which are made in respect to the invention are:—

1. In the production of a multicolour photograph, printing a monochrome positive of a secondary colour corresponding to the first primary, producing a coloured printing member, negative or diapositive, contrasting in colour with such positive, and then printing from said coloured printing member in registry upon said positive an image of, or one which is subsequently dyed or coloured to, a red or other secondary colour corresponding to the second primary.

2. In the art of colour photography the process of making a multicolour photograph from a set of coloured selection negatives which represent the respective red and green or other selected primary colours, said process consisting in printing from one negative, say the red-representing one, a monochrome positive of a blue-to-green or other secondary colour corresponding to the first primary, producing from another negative, say the green-representing one, a coloured printing member, negative or diapositive, contrasting in colour with such positive, and then printing from said coloured printing member, in registry upon said positive an image of, or one which is subsequently dyed or coloured to, a red or other secondary colour corresponding to the second primary.

3. In the art of colour photography the process according to Claim 2 characterised by the resensitising of the monochrome positive of secondary colour corresponding to the first primary before printing thereon or therein the image of secondary colour corresponding to the second primary.

4. In the production of a multicolour photograph according to Claim 1 wherein the coloured printing member is a red diapositive, producing said diapositive by copper-toning a black diapositive to a red colour.

5. A multicolour photograph produced by the process claimed in the preceding Claim 1, Claim 2, or Claim 3.

DECENNIA PRACTICA—COLOUR PHOTOGRAPHY.

Under this heading we apply to the various branches of colour photography the processes of collection and arrangement accorded to some fifty departments of ordinary photography in the "B. J." during 1916. These extracts are from issues of the "British Journal Almanac" of the years 1906 to 1915, and the present series of epitomes thus re-uscitates and brings together in compact form much useful information, otherwise scattered through nearly a dozen volumes. EDS. "Colour Photography" Supplement.

PSEUDO-COLOUR PROCESSES.

Captain W. Laucelles-Davidson has patented a process for producing natural-colour prints from negatives taken in the ordinary way through a screen. In this negative—

- White should be opaque.
- Blue should be semi-opaque.
- Green should be middle density.
- Yellow should be middle density.
- Red should be faint density.
- Black should be clear glass.

A red positive is first made by any known colour process printed from the negative, taking care that only the clear portions of the negative (representing black) and the most faint density (representing the reds) only are printed. This red positive (from the second operation) is registered in close contact with the same negative, and a fresh positive is printed again in yellow or green (by any known colour process) on another surface until the middle density only is printed. A red positive is made first, and then

superimposed on the same negative before printing the next colour (yellow or green), because the red positive is required to act as a light shield, so that it will block out the red density in the negative and prevent it from printing again on the next colour, unless the colours happen to blend, when, of course, the gradation and density of the negative will step in and give the required impure or mixed colour or colours. We now have a red and yellow (or green) positive, each picking out its own colour and mixture of colours. We have simply to superimpose the red and yellow (or green) positives on each other and place them in register with the same negative, and print the next density (blue) by any known colour process in blue, the red and yellow (or green positive) serving as light shields to prevent other densities from printing in the wrong colour. We shall have now three positives in red, blue, and yellow (or green) respectively, each positive picking out its own colour according to the density of the negative, and to make a picture from the negative as true as possible in colour to the

original scene. We print (without any positive shield or shields) a light monochrome positive in black from the same negative (to give black in clear portion of negative), and when we superimpose and register the red, yellow (or green), and blue positives (or in any suitable order or degree of colour) on the monochrome positive the picture will be a complete triad of colour, the monochrome print giving the black, and the red, blue, and yellow (or green) positive giving all the other colours and mixture of colours when registered and superimposed on each other. Alternative methods of carrying out the same idea of the light-shield by photographic and photo-mechanical processes are described.—Eng. Pat., No. 16,104, 1905; "B.J.," Sept 7, 1906, p. 711.

PHOTOGRAPHY IN COLOURS BY PRISMATIC DISPERSION.

This process, which entirely does away with the necessity of colour filters, is based upon the dispersion of the light rays from the image into spectra, which are produced juxtaposed upon the plate. The original idea was first patented by F. W. Lancaster in 1895 (see Patents Chronology, "B.J." Colour Supplement, April 5, 1907, p. 32). He describes a camera for making coloured photographs, in which the image is first thrown by a lens on to a condenser and grating ruled with opaque bars. The rays that pass through the slits of the grating enter another lens containing a prism, the axis of which is parallel to the bars of the grating. Each strip of light is split up into a spectrum by the prism, and the image thrown on the plate is made up of these parallel spectra. A similar apparatus reversed can be used as a magic lantern to project a coloured image on a screen from a transparency. In the "B.J.," January 4, 1904, p. 7, Julius Rheinberg, in ignorance of the above, also described a process for attaining the same end. Professor Lippmann in 1906 communicated to the Académie des Sciences ("B.J.," August 17, 1906, p. 644) a similar idea, which since then has been elaborated or utilised by several workers.

A PIONEER IN COLOUR PHOTOGRAPHY!—A writer in "Photo Era," in the course of a review of colour processes mentions that in 1851 a clergyman named Hill, who lived in New York, startled the world by announcing that he had discovered a method of photographing in natural colours. Almost every newspaper and magazine in the country gave Hill column after column of free publicity because of his statement that, despite his being a poor man with a large family, he had refused offers of all kinds for his invention because he was determined that it should not be used as a monopoly by any one. A clipping taken from a paper published late in 1851, says: "Mr. Hill is pursuing a course which must sooner or later gain him the confidence of his fellow artists. It is Mr. Hill's intention to take out a patent covering his invention, yet he will act liberally towards his fellow-artists."

"Hill finally announced that, after much persuasion, he had been fully convinced that his duty to humanity demanded his publishing a book in which would be described his process. In accordance with this resolve, Hill printed a small leaflet in which was given the contents of the forthcoming volume. The price of the book was to be five dollars—first come, first served—with no favour shown to those of low or high degree. After collecting \$15,000 in cold cash, Hill finally issued a cheaply-printed book on the daguerreotype-process. Thus he proved that, although he might have been a poor man, he was by no means a stupid one; and that, although he might not have discovered a way to make photography in colour, no one could deny that he had found an effective method to make fifteen thousand dollars."

DUST AND THE PAGET COLOUR PROCESS.—When doing some experimental work with the Paget colour process, which necessitated a journey over rather dusty roads for a couple of miles I had during the past summer a rather annoying experience. The taking screen and the panchromatic negative plate were very carefully knocked free from dust in the dark-room before being loaded into the slide—a double book form pattern to which I fitted an extra supplementary spring in order to secure perfect contact between plate and screen. I was surprised to find, however, upon developing my plates, that in two of the negatives the black "dots" instead of being very sharply defined as is essential for a good colour rendering were very diffused

Carbon Tissue for Multi-Colour Prints.—E. N. White has patented pigment tissue coated with a series of layers of gelatine mixtures containing pigments for the production of colour effects by printing from ordinary negatives. The paper is first coated with a mixture containing a white pigment, then with blue or violet, then yellow, and then green or red.—Eng. pat. No. 10,892, 1910; "B.J.," June 30, 1911, p. 500.

Multiple carbon tissue for producing multi-colour effects from ordinary negatives has been the subject of several patents in the past, notably that of Slavik, whose product was issued as "Multico" by the firm of Dr. Hezekiel, Berlin.—(See "B.J.," 1906, p. 66. Ed., "B.J.A.")

Gabriel Lippmann, in a paper before the Paris Academy of Sciences ("Comptes Rendus," July 30, 1906, p. 270), describes the application of the principle of the spectroscope to direct colour-photography. Instead of the single slit of a spectroscope, a series of slits all very close together is used. They are fine transparent lines of a ruled screen of five lines per mm., such as is employed in process work. This screen is fixed to the front of a photographic enlarger, i.e., to a box provided at its extremity with a sensitive plate, and carrying a converging lens at about the plane midway between its two ends. In front of the lens is fixed a prism of small angle, with its edge parallel to the transparent lines of the screen.

The image to be reproduced is projected on the screen, the sensitive plate is developed and put back in place. On illuminating the apparatus with white light an image is seen in colours. Each line of the screen acts as the slit of a spectroscope, and, as the lines are not visible at the distance of distinct vision, the image appears continuous.

(To be continued.)

and in certain areas were absent altogether. The taking screen was not a new one, having been previously used with perfectly good results, but I was led to examine it with a view to tracing the cause of the trouble, especially as the making of a transparency and subsequent registration with a viewing screen confirmed my first suspicions that the taking screen and negative plate could not have been in perfect contact. Careful inspection of the taking screen proved that the trouble was caused by a number of minute particles of dust, which had worked in somehow, between the two surfaces and prevented proper contact and a proper representation of the "dots" in the negative. I afterwards overcame this trouble by making it a practice to bind the two glasses together lightly with strips of lantern slide linen, which ensured a more even contact and also absolutely prevented the entrance of dust. The binding is easily removed by paring it round the edges with a sharp knife when it is desired to separate the plates. I have found that, however good may be the camera case, dark slides, etc., upon a dusty journey foreign bodies will find admittance somehow. In ordinary work such may do little harm beyond a few pinholes, but in colour work for the reason detailed above and also from the fact that owing to the impossibility of spotting them satisfactorily pin holes are to be avoided, some amount of preventive care against dust is an absolute necessity.—EXPERT

WOOD DIFFRACTION PROCESS.—By an error last month the line diagram, Fig. 1, of the paragraph dealing with Mr. H. E. Ives's

improvements in the Wood diffraction process was incorrectly given. The drawing herewith reproduced is that which should have been Fig. 1.

TWO-COLOUR CINEMATOGRAPHY	THREE-COLOUR BROMOL ENLARGEMENTS. FROM NEGATIVES OF THE JULY TYPE
13	15

TWO-COLOUR CINEMATOGRAPHY.

THE making of a cinematograph film in colours all ready for projection is an ideal which has been pursued by several experimenters, and is, we think, greatly advanced towards the commercial stage by a process just patented by Mr. Aron Hamburger, from whose specification, No. 123,786 of 1915, the following particulars are taken. Broadly, the process consists in simultaneous dye-toning of the two complementary colour-sensation monochrome images on the two sides of a band of film and in apparatus for carrying out this process.

The machine shown by way of example in figs. 1 and 2 is provided with means for carrying a double-printed bleached film *a* and passing it between a pair of suitably operated pressing rollers *bb'* by which the continuous bands *cc'* of porous absorbent material charged with the dyeing fluid and the film are fed.

The machine is also provided with guide or tension rollers *dd'*, and at a point beyond the pressing rollers *bb'* there are conveniently a pair of dye-fixing perforated rollers *cc'* emitting dry steam on the dye bands to fix the dye on such portion of the same as is required to be dyed, around which sets of rollers the continuous bands are in engagement. At points intermediate of the tension rollers and the pressing rollers suitable means are provided for keeping the absorbent bands *cc'* suitably saturated with the dyeing fluid.

The film and the dyeing bands are caused to pass slowly through the rolls, the rate being such as will permit of the dyeing being properly effected. The film is then washed off and fixed in the usual way.

In carrying the invention into effect in another form, instead of employing absorbent bands to carry the dyes, a series of frames is mounted in chain form round suitable spring-pressed polygonal rollers. These frames act in a similar manner to those described in the specification of Mr. Hamburger's application No 17882 of 1917, and are preferably closed shallow tanks, the closure of which is effected on the outside by glass plates, and on the inside by jointing material which seals them against the film, which one element of each pair of chains clamps between them.

In figs. 3 to 7, cast brass frames *g* carry brass frames *h*, securing rubber sealing strips *i* and glass plates *j* perforated to con-

nect with inlet and outlet passages *k* for the dyeing fluids. The two halves of the cells are carried respectively around polygonal drums *l*, adjacent cells being connected by a plain link joint *m*, shown especially in fig. 5. The two halves forming a complete cell, one half being carried on one series of drums and the other on a second series, are registered by means of spigots or guiding pins *n* taking into holes, and the frames as a whole are positioned with respect to the drums by projections *p* on the latter

Fig. 1.

entering holes *o* on the former. The two halves of the frames are normally caused to approach by means of a spring indicated by *q*, and a simple linkage *r* can be provided for moving them to and fro. The dye may conveniently be fed from tanks *r'* disposed centrally between the chains of frames around the rollers, and means may conveniently be provided for raising or lowering these tanks; for instance, they can be mounted on standards *s* and held in the top position by swinging link *t*, which can be moved by hand so that the tanks can be lowered into the bottom position. They are raised to cause the flow of the fluid into the tank chambers, and lowered to withdraw the fluid therefrom; or, again, in another arrangement the fluids may be caused to circulate through jots, which play upon the film while it is clamped between the frames. When dyeing has been

effected, the chains are moved on one link, and the operations repeated on the next section of film. The film is also arranged to be fed on through washing, fixing, and drying appliances as usual.

In another method of carrying the invention into effect, the bleaching and pigmenting or dyeing are effected in one operation, by providing a bleaching bath, the composition of which is given below, in which strips of carbon paper or dye gelatine paper are caused to be soaked for a suitable time, say five

gelatine which is absorbed by the silver image during the coincident bleaching and pigmenting process becomes insoluble in water. Then, in the case of carbon paper, this is developed in hot water as usual, the paper floating away or being gently removed, and the resulting mass being treated with the warm water as in the usual carbon process, removing the soluble pigmented gelatine, and leaving the image in colour. In the case of dye gelatine papers cold water treatment is employed instead of treatment by warm water.

Fig. 7.

minutes, on their passage to the two pairs of pressing rolls above described. The two papers and the film are allowed to remain in contact simultaneously with the film to be dyed a sufficient time, and are then fed forward into a position where the carbon paper is brought into contact with hot water for development, or, in the case of the dye paper, with cold water

The required combined bleaching and pigmenting solution for use either with dye bands or carbon pigment paper is prepared from the following ingredients:—

Copper sulphate	4 ozs.
Potassium bromide.....	1400 grs.
Potassium bichromate	180 grs.
Hydrochloric acid	80 minims.

The copper sulphate is dissolved with the potassium bromide in 20 ozs. of water, and the potassium bichromate in another equal quantity of water, with the indicated hydrochloric acid added. The two solutions are then mixed slowly, while stirring well, and the resulting solution is ready for use. The dyes required are for greenish blue, basic methylene blue, which should be as nearly as possible minus red, and for magenta red, basic fuchsia red, which should be as nearly as possible minus green.

(To be continued.)

Fig. 4.

for washing. Simultaneous bleaching and pigmenting is thus effected.

Mr. Hamburger finds that carbon and dye gelatine papers containing the desired colours when applied to a silver photograph image have, in addition to the property of bleaching the silver image, the property of impregnating the bleached image with the colour or pigment contained in them, that is to say, as the silver image is bleached by the solution it is at the same time absorbing pigment or pigmented gelatine from the band or plaster of carbon paper or dye gelatine paper, and by some action, perhaps catalytic, the amount of pigmented or coloured

PAGET COLOUR PROCESS.—It may be said that too little attention is paid by the majority of workers to keeping the taking screens and lens filters in a satisfactory condition. The taking screens should, of course, be protected as much as possible from the action of strong light, which may have a detrimental effect upon their adjustment. I have more than once known of trouble arising from neglect of this precaution. The screens should not be handled more than is really necessary, as their surface is very easily damaged. When not in use they may be kept wrapped up in tissue paper in their original boxes. If, however, in course of time the screen gets dirty or soiled it may be cleaned with a tuft of fluffless cotton wool moistened with methylated spirit. With regard to the lens filter, if this is not sealed between glass great care must be taken not to touch the surface of the gelatine with the fingers, or it will be ruined. I have not found any trouble arising from undue action of strong light, but it is, no doubt, a wise precaution to keep the gelatine filter carefully away from influences that may have a detrimental effect upon it. It should, of course, be protected from dust or damp, as the latter in my experience, tends to alter its colour.

THREE-COLOUR BROMOIL ENLARGEMENTS FROM NEGATIVES OF THE JOLY TYPE.

[It is difficult to find descriptive titles for the particular combinations of processes which are employed by experimenters in colour photography. Mr. S. H. Williams, whose paper before the Royal Photographic Society we reprint below from the Society's Journal, makes a negative through a banded three-colour filter such as that first employed by Professor Joly. He places the negative in an enlarging lantern, and by means of a ruled screen consisting of bands twice the width of the alternating spaces, and the latter the same width as the bands in his negative, he projects upon successive pieces of bromide paper the sets of bands representing the red, green, and blue-violet colour-sensations. Processes of this kind have been employed by Brasseur and Powrie. The element of novelty in Mr. Williams's processes is the means adopted for identifying the bands corresponding with a given colour-sensation when making the enlargement. But quite apart from this contribution to the technique of colour photography, his paper is a very remarkable demonstration of what can be done by an ingenious practical worker, unprovided with instruments of precision, in the way of originating a colour-screen plate and the screen or key-plate necessary for carrying out the process outlined above. Although the fact is not emphasised by Mr. Williams, it is clear that the relative excellence of the results which he exhibited, as regards brilliancy and freedom from the linear structure of the original negative, arises from the spread of the image which is produced when enlarging each separate set of bands upon the bromide paper. Probably the spread is due partly to optical causes and partly to development phenomenon, but if it did not take place to a considerable extent it would be impossible, as is pointed out by Mr. J. C. Warburg in the discussion of the paper, to obtain the solidity of the blacks which was characteristic of the colour enlargements shown. The same phenomenon comes into play in the making of contact copies from an Autochrome on to an Autochrome plate and is the factor which renders practicable what on theoretical grounds would be a process resulting, in the case of printing a positive from a positive, in a very great degradation of the colours by admixture with black.—Ems. "B.J."

The ordinary way of attempting three-colour work consists in making three separate exposures on three separate plates with three separate colour filters—red, green, and blue. The main objection to this is the necessity for the three separate exposures, since, except under the very best lighting conditions, it practically limits the worker to still life, for portraits are almost out of the question when three plates have to be exposed in succession, and the same is true of landscapes which include clouds. To overcome this objection a great many people have spent time upon ingenious devices, the most elementary of which was the use of a camera with three lenses side by side, thus giving the three pictures at one exposure. Unfortunately, the viewpoint of the three lenses differed, and so did the pictures. A modification of that method was to use three parts of the same lens by means of mirrors. But even though one got three pictures from a single lens, this did not eliminate what is known as the stereoscopic effect. Other devices have been suggested from time to time, involving again the interposition of mirrors, but none of them are free from objection.

It occurred to me that a much simpler method of working, and one that would get the three-colour impression at a single exposure on a single plate, would be to use a three-colour filter. Two conditions in the use of such a screen are extremely important, first, that the three-colour screen must be of such a character as to enable us readily to make a separate print from the parts filtered by each of the three colours; and, secondly, that the colour elements shall be so finely divided as to give the effect of a continuous picture.

So far as I know, there is no three-colour screen on the market which fulfils these conditions, and therefore the first thing I had to do to test my idea was to make my own colour filters, and thereby hang a story, which I may tell at a later stage. A screen was eventually evolved. The three colours of which it is composed are red, green, and blue, and they are arranged right across the plate in straight lines, the colours alternating. It is clear, I think, that if we were to expose a suitable plate behind such a screen, one-third of the plate—that is to say, the finely-divided parts which come behind the red lines—will be filtered by the red, another third by the green, and the final third by the blue. If we can readily make a print from the parts which come behind each set of lines, and the lines are sufficiently fine to give the effect of a continuous picture, then we shall be able to get the equivalent of the three-colour impressions either in black and white or in colours complementary

to the colours on the screen, that a worker of the ordinary method gets from his three separate negatives.

In order to carry this out it is necessary to have another screen, which consists simply of black lines and clear spaces. The black lines are the same number to the inch as the lines of each colour in the colour screen, namely, 180 to the inch, or, in the case of the colour screen, 540 lines of the three colours. But the black lines in this other screen are just twice the width of the spaces in between, or equal to the width of two contiguous lines of different colours in the colour screen. I have here models of both the colour screen and of the key-plate, as the other is called, and it will be observed that if I put the key-plate in contact with the colour screen a number of coloured bands appear, due to the colour lines of the screen being crossed by the lines of the key-plate, and the bands can be made wider or narrower as the screen is turned. Ultimately, in a certain position, when the lines of the key-plate are parallel to the lines of the screen, the colour bands disappear altogether. By now sliding the key-plate a little, I can cover up any two colours and expose the other, so that I can get in turn a red, green, or blue impression.

Now, in the case of the negative which has been exposed behind the colour screen, the key-plate makes it possible to cover up, not two colours, but those parts of the plate which have been filtered by those two colours, and to make a print from the exposed portion. I can slide the key-plate along the negative, first exposing from the parts filtered by the green, then, after a slight motion, from the parts filtered by the red, and, finally, from the parts filtered by the blue. That is an operation which can be done by hand, but I have designed and constructed a mechanical way of doing it which reduces the operation to as automatic a movement as most of the operations in photography. I have here a carrier for my enlarging camera with two platforms, on one of which I place the negative, which is held in position by a number of little springs bearing on the edges of the plate, and on the other platform I put the key-plate. On closing up the carrier the two are brought into contact, and I have introduced, by very simple link motions actuated by screws, means of turning and of sliding the one plate in relation to the other.

In operation, therefore, we have first of all the three-colour filter behind which we expose a plate. The negative is mounted on one of these platforms, the key-plate on the other, the apparatus closed up, and the negative and key-plate are brought

into contact. The carrier is put in the enlarger. On looking at the enlarging easel we see a projection of the negative crossed by a number of bands. These are the equivalent of the colour bands seen earlier, and are formed by the lines on the key-plate crossing the lines on the negative. It remains to turn the screw until the bands widen out and ultimately disappear, when one knows that one set of lines is parallel with the other, and then by turning the other screw the key-plate can be moved until it covers up the parts of the negative filtered by two colours, and now I can make an exposure from the parts filtered by the third colour. By moving the key-plate along I get in turn prints from the parts filtered from each of the other colours.

It may be asked how I know which parts I am covering up. We have an easy way of arriving at that information. On the colour screen I have certain marks which I call identification marks. A single mark consists of a break in the blue lines, a double mark of a break in the green lines, and a treble mark of a break in the red. When I am covering up on the colour screen the parts coloured green and red, and only the blue lines are to be seen, I see that single mark because it consists only of breaks in the blue lines. On sliding the key-plate along I become aware of the double lines which consist of the breaks in the green, and on displacing further these disappear, and I see the three marks. These same identification marks are on the negative, only instead of being white marks they are darker. Therefore, on sliding the key-plate across the negative, I know when I see the single mark that I have the parts of the negative which have been filtered by blue; similarly when the double mark is visible we have parts of the negative filtered by green, and similarly again the treble mark indicates the parts filtered by red.

Thus I have from the one singly-exposed negative three separate prints, one of which has been filtered by red, one by green, and the other by blue. From this stage it is possible to work in any one of a dozen different ways. The ozobrome method can be used, as is done in the Raydex printing process, or, instead of using the colour sheets of the Raydex method we can get, still by the ozobrome process, three pictures in plain gelatine, which can be dyed up, and we have what is known as the Sanger-Shepherd process. Or these three prints can be treated as the printing positives of the pinatype method; or again—particularly if we use a paper like the Kodak transfertype—the prints can be bleached to a silver salt which has an affinity for certain dyes, such as silver iodide has, and the prints can be dyed up in three colours complementary to those of the screen, the silver being removed ultimately and the three prints put in register so as to give the colour result.

The method which appeals to me most, however, is the Bromoil method, and the few pictures I have to show are obtained by that method. The yellow, red, and blue prints, complementary to the blue, green, and red of the screen, are bleached for Bromoil, and after they have gone through the usual bleaching processes, they are inked up in printer's ink applied with a brush. My own method of working is something like this: Having bleached these three prints, which are soaking in water, I take out the yellow one, make it surface-dry by mopping, and then by means of a brush ink it up in yellow; when completed I put it on a piece of plain drawing paper, smooth it out, and subject it to pressure (in my own case it is put through the domestic mangle). I have thus transferred the yellow pigment from my bromide on to the drawing paper. The paper bearing the yellow print is now hung up to dry; it is not very wet, but it has absorbed a little of the water from the wet print. I then proceed to pigment up the second print; it is surface-dried, inked-up blue, and then put on the top of the yellow print in register and passed through the mangle—which means that I have transferred the blue on to the top of the yellow. To complete it, I go through the same process with the third

print, inked up red, put it on the top of the print which already bears two impressions, and again put it through the mangle. It is not a long process, occupying, with prints the size I show (about half-plate size), perhaps half an hour.

Mr. Williams then showed a number of results, which were passed round. They included the representation of a colour chart, landscapes, fruit studies, a sunset, landscapes with figures, and a portrait. In some cases on looking closely it was possible to see the lines, but the lecturer said that he could have eliminated them if he had cared to do so. He had one landscape enlarged about three and three-quarter times, and by putting it a little out of focus he eliminated the lines completely. But even though one focussed sharply, the lines were not visible on ordinary viewing, as, for example, at a distance of three or four feet from an exhibition wall.

A large number of questions were then put to Mr. Williams. Asked what increase of exposure was necessary, using the screen, he said that the combination was slightly handicapped in the blue—the panchromatic plate, while much more sensitive to the red than the ordinary plate, was still more sensitive to blue than to red, and therefore blue was handicapped with a slightly orange filter—but he worked the combination, using the three-colour screen in position at $f/16$ (using the language of Wynne's exposure meter), or about one-eighth of the actinometer time as given by Wynne's meter on an ordinary subject at $f/7$. Asked further how many times the usual exposure that would be, he said that as nearly as he could judge on a rough calculation, he should say about twenty-four times. In reply to further questions, he said that the negative plate he used was a Paget colour plate. He used the Paget colour plate and worked it at $f/16$ Wynne.

Obviously the three prints had to be made through the lantern, because he had got to cover two-thirds of the negative each time. One member suggested that the carbon process was necessarily excluded, but Mr. Williams claimed that his methods of working did not exclude any process. When the three prints had been made on paper they could be reversed. Having printed the positive, one could remove it with potassium permanganate and sulphuric acid and develop the remaining parts of the silver. Thus one could have negatives in place of positives, and by working from these, use the carbon process or any similar process that was desired.

Asked what particular method he adopted for registration when superimposing colours, Mr. Williams said that in the registration of the prints he had tried half-a-dozen ways, all of which could be worked, but the easiest was to mark on the back of the negative, somewhere near the margins of the part of the negative he was going to use, a cross at each margin. These would show in the prints as white crosses, and being on the same negative, would be in the same position in each of the three prints. Then he could cut away the prints up to the line and use these as a means of register when transferring his prints. He did not claim that this or any such method would give microscopic register, but it was near enough for practical purposes. His earlier prints were made on ordinary dried drawing-paper. He had never damped it. But on looking at some of the earlier prints it would be apparent that there was a feature about them not altogether pleasing; they appeared rather dead. There was an opacity in the shadows he did not like. This led him to attempt to treat his paper, but he had not yet reached the final stage in his experiments along this line. At present he was treating it with a mixture of celluloid solution and oil containing a white pigment. He put it on with the brush, and he found it overcome that objectionable deadness; also the paper absorbed moisture nothing like so readily from the print. He promised to send the society particulars of his experiments when completed.

THREE-COLOUR BROMOIL ENLARGEMENTS FROM NEGATIVES OF THE JOLY TYPE	18	Photography in Colours by Prismatic Dispersion	20

TWO-COLOUR CINEMATOGRAPHY.

[In the patent specification from which we quote in the following article details are given supplementary to those published a month ago of the processes lately invented by Mr. Aron Hamburger for the production of ready-to-show colour cinematograph film. It will be seen that Mr. Hamburger's invention consists in a process and apparatus for simultaneously printing a colour impression on both sides of a cinematograph film. Although described in the specification as for two-colour it can be understood that the process is equally applicable to the making of a three-colour film.—Eds. "B.J. Colour Photography" Supplement.]

FURTHER details of the manner of carrying out a two-colour process of the kind already described are given in a further specification, No. 123,787, also of 1917, in which details are given not in specific reference to colour cinematography, though evidently they are applicable thereto.

According to this specification, complementary colour negatives (e.g., a red or orange-red value negative and a blue or blue-green value negative), one of which is reversed, are accurately super-imposed on opposite sides of a double sensitised film and photo-chemically printed, and the combined positive produced is coloured on each side practically simultaneously (after bleaching or in a manner combining bleaching and colouring), and preferably combined with a yellow-value positive, prepared preferably by the process of Patent No. 20880 of 1911. The invention also consists in a special dyeing frame for use in connection with such process.

In carrying this invention into effect in one form a red-value negative and blue-value negative are made of the coloured object to be reproduced by photographing through colour screens by means of a camera in the usual way. If these negatives are prepared with an ordinary camera, one of the negatives is reversed. Mr. Hamburger prefers, however, to employ a camera embodying the invention described in Patent No. 28,722 of 1912, in which case he obtains both negatives at the same time, one of them being reversed. These negatives represent the red value of the object and the blue value of the object respectively, and should be practically complementary. They are accurately superimposed in relation to one another upon opposite sides of a doubly-sensitised film, i.e., a film having emulsion on both sides. Each of these negatives is then printed by suitable simultaneous illumination from opposite sides and developed and fixed as usual. When the negatives are truly complementary and of practically the same density, it is found that no protective screening is required if equal illuminations be used, and that the colour values print without interference with one another. The double positive is then bleached, say by the well-

known Traube method. The object of this process is to convert the silver image into a silver salt, which has a high affinity for coal-tar colours. In order to obtain an image more stable and resistant to washing, etc., Mr. Hamburger prefers to employ a bleaching solution made up as follows:—2 fluid ozs. of a solution of 1 oz. of potassium iodide in 9 ozs. of water are added slowly, and with stirring, to 4 fluid ozs. of a solution of 1 oz. of potassium bichromate and 9 ozs. of water. To the resulting solution is added very slowly, and with stirring, 16 fluid ozs. of water containing 80 minims hydrochloric acid. The developed and fixed film which is to be coloured is soaked in cold water and allowed to drain. It is then introduced into the bleaching bath, until the silver in the image is completely bleached. It is then thoroughly washed in cold water, and then in warm water up to 140 degs. F., until all reddish and yellowish stains disappear, and the non-silver spaces are thoroughly colourless and clear. The positive is then ready for dyeing. The positive thus produced is then placed in a dyeing frame, as shown in the drawings.

Two rectangular frames *a a'* of a suitable size for the positive film to be treated are constructed similar to printing frames, but the one is adapted to fit into the rebate of the other, just as if it were the glass of an ordinary printing frame. The rebate of the one frame is provided with rubber *b* or like jointing material, so that the film *c* when pressed against it round the edges will be sealed with a water-tight joint. The second half of the frame is also provided with a ring of jointing material *b'*, and is placed on the top of the film, clamping the latter against the other half-frame all round its edges in a water-tight manner. The outer side of each of the halves of the frame is provided with a sheet of glass *d d'* sealing against the edges of the frames, and thus forming a tank chamber on each side of the film. The two halves of the frame may be arranged for rapid opening and closing by means of hinges *e* along the bottom edge and wing nuts and screws *f* on the top edge. The tank chambers on each side of the film are provided with outlet passages *g* at

their lower ends, and these are controlled by suitable cocks or valves *h*. Inlets *ii'* are provided at the top edges of the tank chambers, for the admission of the dyeing fluids. Means are also provided for the outlet of air by the valves *kk'* as the fluid

Fig. 1.

Fig. 2.

is introduced. The air exit valves *kk'* may be adapted to be closed at will. To allow for the sagging of the film, in case one fluid should be introduced slightly before the other (the dyeing still being substantially simultaneous), the inlet pas-

sages may each be provided with a small reservoir not shown, which will hold fluid displaced from the tank chambers.

The film introduced into the dyeing tank just described, and clamped therein, is dyed by the introduction of the appropriate dyeing fluids on each side. The film may thus be simultaneously dyed on both sides. The dyeing fluids are then run off, and the positive thoroughly washed, until all the non-silver parts are cleared of dye. Fixing is then effected in hyposulphite of soda, containing 5 per cent. of tannic acid, and the film is then washed and dried in the ordinary way.

The positive film thus obtained is then combined by superposition with a yellow-tone positive representing the yellow-colour value of the object photographed. Where a two-colour result only is desired, a positive similarly made from orange-red and blue-green value negatives and dyed relatively blue-green and orange-red, may be mounted on paper or used as a transparency. The yellow positive is preferably obtained by the process described in the Patent No. 20880 of 1911, and the combination gives a practically perfect colour reproduction of the original object in natural colours.

In carrying this invention into effect in another form, instead of separately bleaching and dyeing the positive images printed on the film from complementary colour negatives, both bleaching and pigmentation or dyeing may be done simultaneously by taking carbon papers or dye gelatine papers containing the desired colours and soaking them for five minutes in a bleaching solution according to the method already described in Patent No. 123-786. ("Colour Photography" Supplement, April 4, 1919.)

THREE-COLOUR BROMOIL ENLARGEMENTS FROM NEGATIVES OF THE JOLY TYPE.

[The concluding portion of the paper read before the Royal Photographic Society by Mr. S. H. Williams contains the latter's replies to questions which were asked, but for the most part deals with the extremely ingenious methods devised and employed by Mr. Williams for the making of the original three-colour banded filter with which his negatives were made. Everybody who knows anything of colour photography understands the nature of the Joly colour-filter, but few perhaps have taken the trouble to make one for themselves by methods which, as will be seen, are within the competency of a worker possessed of plenty of patience and something more than the average ingenuity in the use of tools.—Eds. "B. J. Colour Photography" Supplement.]

ANOTHER question was asked as to whether it mattered in what order the pigments were put on. Mr. Williams said that it was usual to put the yellow on first because, of the three colours, the yellow was the most opaque. But so far as his experience went it did not matter very much in the ordinary way which colour was put on first. The order generally followed was yellow, blue, and red. As to whether there was any difficulty in getting the right shades of colour, he said that here arose one of the advantages of the Bromoil method. But as it only took about half an hour's work at the sizes shown (about half-plate size) to make a complete print, and if that print was not what the worker wanted, he could make a second one, and profit from the lessons of the first. If the first print was deficient or excessive in any particular colour, he had only to modify his method accordingly the next time. There was probably more difficulty in getting uniform results by the Bromoil method than by any other.

On a member raising a question as to additive processes, Mr. Williams said that additive methods did not come into consideration at all. Two methods were in vogue for combining colours, one the additive method in which the primary colours were red, green, and blue, and yellow was a secondary, obtained by mixing green and red, but his method, like most methods on paper, was a subtractive method, and the three primary colours were the painter's primaries, namely, red, yellow, and blue. Additive considerations, therefore, did not interest him at all in this method. So long as his three-colour elements in the colour filter were efficient, he need not bother about the production of a correct additive result.

He was not concerned with transparencies, although he had made them, and had intended to bring some results to that meeting. When he talked about registration, he simply meant registration for the subject and not for the lines. That the method was on a right basis he could only argue from the general success of the examples shown. In some cases, on looking closely, the lines of the negative might be seen, but in others they would be entirely absent, because he had taken special precautions to blur them. The reason for the difference in colour of the two prints from the same negative, to which a member drew attention, was that, as usual, he had been experimenting. In one case he might have given the three prints absolutely the same exposure, while in the second set he gave the red a little longer, which meant that he had a red note predominant all through the picture. He had worked with screens varying from 150 to 250 lines of each colour to the inch, but there was a special reason why he had ultimately fixed on 180 lines, which he would explain presently, if he had opportunity to describe the making of the screen. The prints he had brought forward were absolutely straight prints.

A member raised the question as to whether it was possible to produce blacks, or, indeed, to reproduce a given chart correctly; and another member (Mr. Warburg) said that if the image were not blurred a black could not possibly be obtained. In order to get a black, each of the lines, said Mr. Warburg, must be blurred to three times its original space; the blur seemed to be essential to this method of work. Mr. Williams said, in reply, that he did not claim for a moment that the

Bromoil method, at any rate, would give every colour with absolute correctness. The inking-up was so largely a personal matter that he would not guarantee it in any instance. Even the painter had to compromise. It was not possible to put on paper in black and white alone, to say nothing of colour, the range of tones between the darkest shadow and the highest light. They had to compromise. But as to the production of black, he thought that black could be reproduced nearly enough for pictorial purposes, because in outside work black never entered. A sufficient depth of colour could be got, by either the Ozobrome or Bromoil method that approximated to black for all pictorial purposes. As to the point raised about the three lines not giving a black by reason of their not covering up the space, if the member tried this method he would find when he examined his prints that in the darks the light-action had spread over beyond the lines; in fact, in the very darkest parts of the picture the lines would be absolutely lost. That was what happened in the very dark portions of the picture—the lines widening out until in most cases they joined up together and gave in the very dark an almost uniform black, and hence a continuous picture in the darks.

Mr. Williams then described his experiments in making the three-colour line screens. He said that for the making of the colour screens another key-plate was necessary, only, instead of being a key-plate like the one he had shown, with black lines twice the width of the space, it was the reverse, i.e., the black lines were half the width of the clear space. He was told that screens could be purchased, but on applying to a firm who had made screens for process blocks, he was informed that while such a screen could be made for him, it would be necessary to send over to America, and they could not be promised for at least nine weeks. Thereupon he decided to make his own screen. To rule it with a diamond point was out of the question, and he proceeded to try another method of ruling. The first thing he did was to take two pieces of printer's brass, mounted on two strips of plate glass to keep them flat, and he spent some hours grinding the edges. This gave him the means of getting a slit of light, by mounting the brasses on the parallel ruler principle. He then described his arrangement for exposing through the slit and moving the plate along as required. He had two laths about six feet long, to the bottom of which was attached the board carrying the photographic plate. He attached a screw to this board, and at the other end of it he had a weight passing over a small pulley. By means of the screw he was able to shift the plate by almost infinitely small distances. The number of threads per inch in the screw was fifty. A complete turn of the nut of the screw would therefore move the plate by one-fiftieth of an inch. The nut had four notches in the fashion of a ratchet-wheel, and therefore to move it one-quarter of a turn as guided by one of these ratchets would shift the plate one-two-hundredth of an inch. This arrangement he yoked up with his enlarging apparatus. On giving an exposure through the slit, a line was traced on the photographic plate, and on moving the screw a quarter of a turn, and giving a second exposure, a second line was traced one-two-hundredth of an inch distant, another movement and a third line was in position, and so on right across the plate. He could go all the way across a quarter-plate in twenty-five minutes at 200 lines to the inch.

His first screen thus constructed was rather like a Scotch plaid. It was marked by bands both vertically and horizontally. The one set of bands he could understand, for they were due to the lines not being exactly straight, and by dint of hard work he got rid of these ultimately. But the bands in the other direction were a more difficult problem. He could not think what caused them, until at last he came to the conclusion that they must be due to the fault of the shutter not always working at the same speed, and therefore the exposures were not quite uniform across the plate. He thereupon set to work to invent

another shutter, and he made a focal-plane shutter on a pendulum with a piece of cardboard at the bottom sufficiently big to cover the slit when hanging at rest, but sufficiently far out of the centre to ensure that when the pendulum was swung, it swung past the slit. This device enabled him to give absolutely the same exposure every time. Shutters not only varied from the speeds given by their makers, but they did not always work at the same speed. The shutter he improvised, however, did so. But it did not get rid of the bands! It made a big improvement, but the bands remained.

By careful watching he then discovered that the gas supply he was using was inconstant in its pressure. Having as neighbours both a gas manager and an electrical engineer, he called them into consultation. The gas manager provided him with half-a-dozen kinds of gas governors, but however well they served their proper purpose, they did not answer in this emergency. The electrical engineer brought him an assortment of batteries and so forth, by which he claimed that a constant light could be secured. He put the plate on, ruled half-way across it, then interrupted the work, switching off the light, and completing it again after an interval. In the result there were no bands—except one! What had happened was that during the process the battery had weakened, so that the lines on the plate had grown slowly and imperceptibly fainter, but when he stopped and gave the battery a rest, it recovered, and the lines began again at the original strength or thereabouts, so that the break was noticeable. Therefore this was another uncertain light source. He could, of course, have eliminated the band if he had gone right across the plate at one sitting, but the lines in that event would have been thicker on one side than on the other.

Ultimately he got over the difficulty. He got out a cocoa tin, through the bottom of it put two tubes, one of which he connected up by an india-rubber tube to his enlarger, and the other he connected up with the gas supply. In this was placed a smaller cylinder, inverted, and having weighted it with a strip of lead at the bottom, he put some water in the larger vessel, and so adjusted matters that the weight of the smaller tin determined the pressure of gas that he was using. If he got his gas at too high a pressure the gas would bubble out at the bottom. To the tap controlling the supply of gas he arranged a quadrant, and then by means of a very flexible cord and a little pulley he connected it with the floating cylinder. As this cylinder tended to rise, the weight of the sector brought it down and automatically closed the tap, that is to say, the width of the tap was regulated by the height of the cylinder, and the weight of the cylinder determined the pressure of gas supplied. The constancy of gas supply with this arrangement was such that he could make a test for a trial strip on one day and expose it on the next, because he knew that when he turned on the tap he got a constant light.

In this way he had ruled screens up to 250 lines to the inch, but the number of lines was limited to a large extent by a thing he could not control, namely, the waviness of the glass. He had come to the conclusion that 180 lines to the inch of each colour would be sufficient. He found out later that there was a firm in England who made these screens. F. E. Brown and Co., of Leicester, undertook to make him one specially for 25s., and when it was remembered that these screens had to be ruled with a diamond point and etched so as to be deeper still and then filled in with pigment, the charge could not be called excessive. In the first that arrived, the relative widths of lines and spaces were not absolutely correct, and the firm made him another, which was smashed in the post, and then they made him a third, which gave a good result. Nevertheless, he did not regret his experiments along the same line.

From this point the making of a colour filter was comparatively easy. The first thing to do was to coat a piece of glass with celluloid, and then to coat it thinly with bichromated glue.

In order to get a thin enough coating he used a whirler. The bichromated glue was poured on then with a glass rod, leaning just on the edge, the glue was spread all over the plate, it was whirled round so as to leave nothing but an excessively thin film, the remainder being thrown off into the sink below. It was whirled until it was dry, and the next thing was to expose it to light under the printed key-plate. On this gummy coating, the parts which came behind the clear spaces, being subject to light action, became insoluble, and the parts behind the black lines still remained soluble. Then it was put into water and these insoluble lines washed off. All that remained to be done then was to put it into a spirit solution of dye, and in the parts where it was not protected by the gum it took the dye, and where

the gum covered it, it did not take the dye. In this way a set of lines was obtained in one colour, covering one-third of the plate. The insoluble glue was sponged off. After coating again with glue a print was taken a second time, only not quite in the same position—it was moved the width of a line, which was $1/540$ th of an inch. This second printing, therefore, was made $1/540$ th of an inch from the first, developed in the same way, and put into the second solution of dye, which gives a second set of lines, in a second colour, side by side with the first set. We have now two-thirds of the plate dyed in two colours and one-third still to be dyed. Again sponging off the insoluble glue lines, again coating all over with glue and a third printing, etc., gives the complete filter.

DECENNIA PRACTICA—COLOUR PHOTOGRAPHY.

Under this heading we apply to the various branches of colour photography the processes of collection and arrangement accorded to some fifty departments of ordinary photography in the "B. J." during 1916. These extracts are from issues of the "British Journal Almanac" of the years 1906 to 1915, and the present series of epitomes thus resuscitates and brings together in compact form much useful information, otherwise scattered through nearly a dozen volumes.—EDS. "Colour Photography" Supplement.

PHOTOGRAPHY IN COLOURS BY PRISMATIC DISPERSION.

(Continued from page 12.)

It is necessary that the prism fixed in the apparatus shall have an angle so small that each spectrum has a length less than the inter-linear space, otherwise the spectra encroach on each other. It is also essential that the photographic plate occupies exactly the same position as during exposure, a condition which is easily fulfilled in the case of solidly constructed apparatus. If the positive is moved in its frame, the colours rapidly change; if it is turned, there is a coloured moiré effect. On bringing the plate back to its original position these effects disappear.

Rapid commercial orthochromatic plates may be used, and the exposure is much shorter than in the interference process.

It will perhaps be possible to improve this process so as to avoid the use of an apparatus to observe the colours, and to make the plate sufficient in itself.

Suppose that a sensitive plate be placed in an ordinary camera, without a prism, but with the interposition of a ruled screen, and suppose that on the screen (which, we will say, has 5 lines per mm.) we superpose a grating of 500 lines per mm.; each luminous point thus projected on to the screen then spreads as a spectrum, and is photographed. On applying the screen, with its grating, to the developed positive, we should see the colours of the original—that is to say, if the eye can occupy the place of the lens.—"B.J.," Aug. 17, 1906, p. 644.

M. André Cheron describes his arrangement as follows:—Using a screen with an opaque line of $1/5$ mm. broad, two cameras, as

T, screen; V, micrometer screw; P, prism; S, cliché; L, magnifying glass.

shown in the diagram, are combined—the first intended to form on the screen, by means of the first lens, the image of the object; the second intended to re-take this image in lines by a second lens (in front or behind which is the prism), and to project it on

a photographic plate in a series of spectra side by side. The lines of the screen are very close together; the angle of the prism is much reduced (2 degrees 30 minutes). Focussing is effected by means of a micrometer screw, which shifts the screen minute distances to the right or left. Two magnifying glasses are employed and are absolutely necessary, the one behind the screen to make the rays converge towards the second lens, the other behind the second lens to converge the rays striking the positive to the observer's eye.—"Phot. Couleurs," Nov., 1906, p. 89; "B.J.," Nov. 16, 1906, p. 904.

André Cheron has further improved the apparatus for the prismatic dispersion process [see "B.J.A.," 1908, p. 714]. The unequal sharpness of the spectra over the whole surface of the image in consequence of the different angle of the rays falling on the prism is remedied by increasing the focal length of the second lens so as to reduce the angle at the edge of the plate. The apparatus, however, measures 43 ins. in length, although less than $4\frac{1}{2}$ ins. each way. For convenience of carrying it is made in three sections, each about 14 ins. in length, and hinged so that one section folds over another to the total dimensions of about 14 ins. long, 13 ins. high, and 6 ins. thick.

Connected to the first section by a bellows is the board for the first lens, at the focus of which are placed the first single lens and the screen. The whole is mounted on a board which can be moved backwards or forwards from the outside of the apparatus by a rack

O, O', lenses; M, single lenses; T, screen; C, C', rack and pinions; R, R', hinges; P, prism; Pl, plate; L, L', micrometric screws; V, eye-hole.

and pinion. The middle section contains the second lens (long focus), also mounted on a movable panel.—"Phot. Couleurs," Nov., 1907, p. 161; "B.J." Colour Supplement, Jan. 3, 1908, p. 3.

A further patent for the prismatic process is that of F. Urban (Eng. Pat. No. 8,723, 1907.—"B.J.," Nov. 15, 1907, p. 869).

(To be continued.)

PRIZMA COLOUR CINEMATOGRAPHY.—The proprietors of this process, Messrs. Prizma Inc., 11, East Fourteenth Street, New York, write as follows:—In the issue of the "British Journal" of February 1, 1918, our late friend, Alfred S. Cory, unintentionally gave you some notes re the Prizma motion picture films which are not correctly stated. Prizma has since December 28, 1918, been releasing films of the kind described in the last paragraph of the article to which we refer above. We have not given out any detailed description as to our method of working, nor are we ready at this writing to do so, not because of patent reasons, but because certain changes will be incorporated in the films shortly. Our plant has only a limited capacity; we cannot supply the demands of the

American market this year, so that it is not likely that films will go abroad for some time. So far as our technical methods are concerned, we prefer only to say:—(1) Negatives made in two complementary pairs as per our English patent. We have never taken any two-colour negatives. (2) Positives have two superimposed records on each area, one set that of the orange and red records coloured with a single uniform colour, and the same applies to the green-blues. The films project at the customary speed on any standard projector. No attachments of any kind. These positives have been showing for twelve weeks at the Rivoli Theatre in New York City and in nearly 100 cities of the United States since December 28. Ten subjects have been released to date.

WHERE WE STAND IN COLOUR PHOTOGRAPHY.

THE circumstances of the past four and a half years have necessarily been very unfavourable to progress in arts such as that of colour photography, and therefore there may be many readers of these lines in distant parts of the world for whom, at the present time, the so-called "colour plates," producing colour transparencies, stand for what they understand by "colour photography." But these screen-plates, the Autochrome and the Paget, admirable as they are, represent only a special form of a colour photographic process, though certainly for the purposes of the ordinary photographer they are the chief materials for the making of photographs in natural colours. Hence some review of what has been done and of what may be done along other lines may be of interest to many whose acquaintance with colour processes is of comparatively recent date.

There is no need on this occasion to go back as far in the history of colour photography as the processes chiefly due to the inventive and mechanical genius of Mr. F. E. Ives, now of New York, except to say that the optical colour effects which were produced by his Kromskop and lantern Kromskop were probably as perfect renderings of colour as have ever been produced. Yet beautiful as they were, public taste naturally asks for something more tangible than an image upon a lantern-screen or the optical assemblage of three separate images in a viewing apparatus. The public wants, or thinks it wants, prints in colour, and still nurses a qualified dissatisfaction that the results by the Autochrome and Paget processes are obtainable only as glass transparencies. Here, perhaps, a word may be said on the purely human element in the case. We need to distinguish, in forming an estimate of the value of any process of colour photography claiming to yield paper prints, between the requirements of the purely amateur photographer and of the people who would use such a method for commercial purposes such as portraiture, etc. The amateur undoubtedly would welcome with delight a colour process, even one with imperfections if it involved no more delicate manipulation than that necessary in ordinary black and white photography. In the case of the professional maker of portraits, it is to be considered that at present he has at his command processes of colouring which in many cases are not expensive and which, moreover, possess the very greatest latitude, enabling him to produce results beyond the powers of a hard and fast colour process and for commercial purposes more useful. In judging the results

by any new colour process the judgment must be entirely on their merits, and after elimination of any kudos attaching to them, from the fact that they are made by purely photographic methods instead of by the skill of a colourist. One could perhaps sell colour photographs for a little while as curiosities, but the experiment has been tried, with the result that the public was found to judge always by results and was not particularly concerned as to how they are got.

When we review the methods which have been used for making actual colour photographs on paper by the so-called subtractive processes, we see that a method capable of being reduced much more fully to a working system is necessary before any such process is likely to come into general use either by the professional or the amateur. No doubt many readers of this article have heard of colour prints by the Sanger-Shepherd process, though few no doubt, unless they have worked the process for themselves, have seen any. A process capable of very fine results, but calling for a degree of care and observance of detail beyond the inclination of the amateur in these hurried days and commercially too elaborate for the professional. Very much the same may be said of the making of three-colour prints by the carbon process which also, in expert hands, has yielded altogether beautiful results. In the form of the Raydex process, in which pigmentation is done according to the Ozobrome method, three-colour carbon printing has obtained a measure of simplification, one element in which is that the printing is done in the first instance on bromide paper and does not require daylight at any stage. When we have mentioned these three processes, we have perhaps singled out those which yield beautiful three-colour prints from the sets of colour-sensation negatives, but which nevertheless are processes for the few. We should hardly be inclined to include Pinatype among them for the reason that the best three-colour prints by this process which we ever saw had a "dye-y" look. The process for the purposes of three-colour printing may, at any rate, be said to be dead, if it was ever really alive.

On the other hand, within the past few years progress has been made in giving a greater facility to these methods in which three-colour images are assembled in register to form the print in natural colours. Mr. Ives has done much in removing difficulties of manipulation by his invention of the Hichrome process, the development of which has no doubt been hindered by

look the transparency in position. The groove of the carrier also avoids damage to the binding of the transparency and keeps the surface of an unprotected negative or positive clear of any other part of the apparatus which could damage it.

In Fig. 3 is shown the position of the apparatus when used as an illuminating device for making lantern-slides by reduction and similar work. The several parts of the apparatus fold compactly together, and are contained in a cabinet, which is also fitted with a drawer made to hold rigidly any number of transparencies up to 112. Space is provided for carriers, and the whole outfit, although no more bulky than the average microscope case, furnishes the colour photographer with the means of looking at his results under the most favourable conditions and of taking them conveniently to the

Fig. 3.

house of a friend. We understand that Mr. Morton is having the apparatus made in the best style and placed upon the market, but any inquiries as to when or where it will be obtainable should be addressed to him at 97, Chesterfield Gardens, Haringay, London, N.

NOTES ON THE PAGET PROCESS.

THAT photographers fail to obtain correct colour rendering when working the Paget colour process is, in my opinion, due to the fact that they overlook for the most part the importance of making a satisfactory transparency. If this is made too weak the result is, upon the final registration, weak in colour and lacking in brilliance; while if the transparency is made too dense or vigorous a totally false sense of colour is introduced; in the latter case, say, a pale yellow primrose is rendered as a flower of a deep orange hue. This is, in my opinion, the most important point in the whole process, and it is worth any photographer's while who intends to work this process to make a set of transparencies from the same negative, which should, of course, be of good quality, but of different depth and vigour. Registration will show almost at a glance which is the correct density. In passing, I may add that it is a wise rule always to expose the negative plates by meter and develop by time and temperature, thus ensuring negatives of a uniform quality. This part of the process becomes, as it were, standardised, and the worker need have no fear of his results, but may produce a perfect colour picture from each exposure. With regard to making the transparency, it is well to note that if this is to be projected through the lantern it should be less vigorous than when the picture is to be viewed in the hand. The matt ground plates also require to be slightly more dense than those with the clear emulsion.

Though this is, in my opinion, the most prevalent cause of weak or false colours, it is not the only point that needs to be taken into account. The other day I was consulted by a photographer with reference to some colour pictures of a group of anemones. These brilliantly coloured flowers were rendered very weakly in the transparency, and for some time I was at a loss to suggest the reason. The negative was of good quality, and the transparency showed nothing to complain of, being on the vigorous side. Subsequent investigation showed, however, that the exposure was made in a rather poorly-lighted room, which did not render the flowers at their best, with their full brilliance and tonal value. It is necessary to see that the lighting is such as emphasises the colours of

the subject at their best and brightest, or the exposure should be, if possible, deferred until another time. Another point to be noted is that, while every attention may be given to the technique of the photograph, the lighting must be observed, or the plate may give a truer rendering of the image than did the photographer's own vision of exposure. In this the Paget process is the same as the other screen plate processes.—R. M. F.

BOOKS ON COLOUR PHOTOGRAPHY.

PERHAPS the enquiry most frequently received by the editors of this publication is for a recommendation of the best textbook of colour photography, which very often is not an easy question to answer unless the requirements of the questioner are particularly known. This arises from the fact that the literature of colour photography is scanty. Moreover, it has received very few additions during the past ten years. Of the Autochrome process, a booklet is issued in English by the British agent for the plates, Mr. T. K. Grant, 89, Great Russell Street, Bloomsbury, London, W.C.1. There is no doubt a corresponding edition in French published from the headquarters of the firm of Lumière-Jougla Monplaisir, Lyons, France. The makers of the Paget plate, who issue literature on its use, are the Paget Prize Plate Company, Ltd., Watford, Herts., England. Apart from these makers' pieces of literature, the only book at present in print which deals both with the principles and practice of the colour screen-plates is "Photography in Colours," by Dr. G. Lindsay Johnson, the third edition of which was issued in 1916. The book includes descriptions of other screen-plates, not now on the market, and is also a treatise, written in a style characteristic of the author, on processes of colour photography in general. If not entirely free from literal errors and errors of opinion, it contains, nevertheless, the best general survey of methods of photography in natural colours which is at present obtainable.

Of textbooks on the general principles of colour photography and of methods of carrying them out according to the so-called additive and subtractive systems, there are two, neither of which are still in print, although, no doubt, obtainable through second-hand booksellers. The first of these two books is "A Handbook of Photography in Colours," by Thomas Bolas, Alexander A. K. Tallent, and Edgar Senior, published by Messrs. Marion and Co., in 1900. Mr. Bolas's portion is a very able review of the development of colour processes; Mr. Tallent's is a textbook in itself on the principles and practice of three-colour photography; but Mr. Senior's still contains the most practical working instructions for the Lippmann method of colour photography by the interference process. This book also is out of print, but not badly out of print; some dozens of copies were "remaindered" a year or two ago by Messrs. Foyle, of Charing Cross Road, London, W.C.2, so that it is a book which should be obtainable without much difficulty. The second of these is "Natural Colour Photography," by Dr. E. Koenig, translated from the German by E. J. Wall, and published in 1906 by Dawbarn and Ward, Limited. This book, written while the Autochrome process was still in an experimental stage, and no more was known of it than had been published in the makers' specification, naturally has very little to say on the one-exposure colour plates, although it briefly touches upon the work of Joly, and even on the Powrie plate, which for a while obtained some prominence. It is, however, a fairly comprehensive manual on the methods of producing colour prints by the assemblage of three colour monochromes.

A work somewhat similar to Koenig's is "Three-Colour Photography," by the Austrian officer, Baron Von Hübl, translated by H. O. Klein, the fourth edition of which is published by Messrs. Percy Lund, Humphries, Amen Corner, London, E.C.

About the only other manuals which may be mentioned are the issues No. 128 and No. 147 of the "Photo-Miniature," published by Tennant and Ward, 103, Park Avenue, New York. The first of these, issued in 1913, is an explanation of the modern methods of obtaining photographs in colours; the second, issued in 1916, is a practical manual on the working of the Autochrome and Paget processes, with some brief notes on the Ives "Hicro" and the Kodak "Kodachrome" methods. Both these manuals also are out of print.

AUTOCHROME PHOTOGRAPHY BY ARTIFICIAL LIGHT. By Charles J. Belded.....	25	DECENNIA PRACTICA—COLOUR PHOTOGRAPH.....	27
SIX-COLOUR CINEMATOGRAPHY	26	CORRESPONDENCE—The Bleach-Out Process	28

AUTOCHROME PHOTOGRAPHY BY ARTIFICIAL LIGHT.

Notes on the making of Autochromes by various artificial lights, contributed to the "Camera" by an American colour worker.

THE screen-plate method of natural colour photography, whether it be the Autochrome, Paget, or any other practical process, has long since ceased to need introduction or explanation either to the professional or the amateur photographer; but like a great many other branches of photography, there are certain phases of natural colour work that have received the attention of only a few experimenters. This is perhaps only to be expected, for the ramifications of the process that produces all the colours are bound to be greater than those of a process whose results are in monochrome, and the problems of the former will, of course, require more detailed study.

The Autochrome process which was placed on the market some twelve years ago has enjoyed a widespread and deserved popularity chiefly among non-professional photographers, although a considerable number of studios have, from time to time, taken up Autochrome work in portraiture as a side issue. The bulk of Autochrome photographers work the process purely for the pleasure to be derived from it. This condition has been brought about chiefly by the fact that the colour plate is a little more difficult in manipulation than its black and white brother, both in the taking and the developing, and the impression has been gained that its application is too limited for professional workers. This is perhaps true, to a certain extent, just as it is true in monochrome work that the best results are obtained only under right conditions of atmosphere and lighting; but it has been the writer's experience that the Autochrome has far greater possibilities than is ordinarily supposed. During the past few years the scope of commercial photography has expanded steadily in all directions, but workers in this field have been slow to recognise the opportunities offered by photography in natural colours. The supposedly restricted field of colour photography is largely responsible for this condition, and a process that is not of universal application does not readily find favour with the commercial photographer.

Volumes have been written on the exposure and development of the Autochrome plate under normal conditions of lighting, with the result that this phase of the subject is pretty well understood. After a little experience, the percentage of

failures with landscapes or other out-of-door work need be but small, notwithstanding that these plates require a very exact exposure for good results. Even more certain results may now be obtained in portraiture by the use of certain brands of flashlight powders manufactured especially for use with Autochrome plates. By using a given weight of powder, under fixed conditions, the uncertainty of exposure is eliminated and any variation in quality or intensity of light is dispensed with. Exceedingly beautiful results may be secured by this means, and detailed instructions for manipulating the plates under these conditions are readily obtainable. When, however, there arises the problem of making an Autochrome by other light than daylight or flashlight, the average photographer will probably throw up his hands without giving it a thought. Thus, a very interesting and what could be to the commercial photographer a very profitable field is allowed to remain almost untouched. Production of the unusual in photography, as in any other art, is always well repaid, and places the work of the originator on a plane above the majority.

It is not the purpose here to discuss the theories of light and colour as applied to the Autochrome plate, but to suggest merely what may be accomplished practically and simply under conditions of artificial illumination. It need hardly be stated that the colour rendering of an Autochrome is entirely dependent on the spectroscopic qualities of the light that reaches the plate. Only too often have most of us been reminded of this fact by the weirdly blue results obtained when the compensating light-filter has been forgotten. This filter is employed for the purpose of correcting the predominating blue-sensitiveness of the plate, and the colour of the screen used for daylight exposures is such as to cause the colour-rendering of the plate when viewed by daylight to be a very close reproduction of the original subject. It is not difficult, therefore, to imagine that any change in the quality of the light would require a change of screen. This is brought out strongly in the rendering of deep shadows. To the artist all shadows are blue, for in nature black does not exist, and this fact is always exaggerated by the Autochrome. The principal reason for this is that the shaded portions of a picture are illuminated by light reflected

from objects which alter its composition; therefore, the balance of the light-filter is destroyed, and strange and unexpected results are often obtained in reproductions of objects illuminated by light reflected from a coloured surface.

A large number of formulæ have been suggested for Autochrome light-filters for use with various illuminants, but the making of a light-filter is an exceedingly delicate and exact operation. It has been the writer's experience that by the judicious use of two or three standard filters excellent results may be obtained under nearly all conditions. In the first place, there is the daylight screen; secondly, there is the so-called "Perchlora" screen adjusted for use with the "Perchlora" flash powder; and thirdly, the magnesium screen for giving correct colour values in exposures with magnesium powder. All of these screens are readily obtainable and are standard products of the manufacturers of the Autochrome plate. After a few trials along the lines to be suggested, it will be found that beautiful effects may be obtained by artificial lighting.

One of the first problems that baffles the Autochrome worker is the photographing of interiors. The difficulty here arises from the altered colour rendering of objects illuminated by light reflected from some coloured surface and also from the inability to get daylight into some remote corner. Artificial lighting of the dark corners may suggest itself, but the false reproduction of colours will be obvious. A very simple solution is found by making one exposure by daylight with the regular screen, then drawing the blinds and lighting the dark portions artificially, using the "Perchlora" screen in place of the daylight filter. A very haphazard sounding procedure to be sure, but in the writer's experience productive of excellent results. In a number of cases fireplaces have been photographed in this manner, with glowing embers reproduced very faithfully. Brightly burning logs may be photographed successfully on an Autochrome plate by exposing for fifteen minutes at $f/8$ through a "Perchlora" screen.

Making Autochromes of electric fixtures is an interesting undertaking and not as difficult as it might at first seem; in fact, the first plate the writer exposed on a subject of this character proved to be a perfect reproduction. An exposure was first made on the fixture lighted from the inside by its own incandescent bulbs. With the lens working at $f/8$, a

fifteen-minute exposure was given, half of it with no filter at all and half with the "Perchlora" screen on the lens. Two charges of "Perchlora" flash powder were then set off on either side of the camera; the colour rendering in the result was almost faultless.

During the Panama-Pacific Exposition I had occasion to make a considerable number of Autochromes of the night illumination, this feature of the Exposition being of a most spectacular, yet artistic nature. The buildings, in which were incorporated wonderful harmonies of colour, were illuminated at night by an indirect lighting, which produced an inconceivably beautiful effect. Autochrome exposures, through the regular daylight screen, were, of course, out of the question, and as an experiment an exposure was made with the "Perchlora" screen. The result was most satisfactory. With the lens opened to $f/8$, well-nigh perfect results were obtained by exposing on the buildings between three and four hours, depending on the brilliancy of the light. In a few cases, short exposures were made before dark with the regular daylight screen, and completed with the "Perchlora" filter after the lights were turned on. This method proved even more satisfactory than the first, and the added trouble was fully repaid.

In making Autochromes of subjects lighted partly by electricity and partly by daylight, it has been found that the "Perchlora" screen gives very nearly perfect colour rendering. In cases where daylight predominates, the magnesium filter produces the best results. Where most of the illumination comes from incandescent lights, exposures may be made partially through the "Perchlora" screen and partially with no screen at all.

The mode of procedure which has been suggested will undoubtedly seem to be more or less of a "hit or miss" and a somewhat expensive process, but having been worked out on a practical basis, it has proven most successful and has produced results which the average Autochrome worker would scarcely believe possible. Its success is, of course, largely a matter of judgment and a little experience; but the rapidity with which accuracy of judgment is acquired will be surprising. The very exact exposure required under ordinary conditions seems to disappear and a considerable latitude will be found within which excellent plates may be secured.

CHARLES J. BELDEN.

SIX-COLOUR CINEMATOGRAPHY.

[An additive process of colour cinematography, similar in its general principles to Kinemacolor but differing from the latter in the sequence and selections of the colour sensations, has been patented by Mr. Joseph Shaw, 8, South Second Avenue, Mount Vernon, New York, whose specification, No. 126,220, contains the following detailed description of the process.—
Eps. "Colour Photography" Supplement.]

In the production of moving pictures in colours as hitherto suggested, a rotary band screen was provided having arranged thereon three or more filters in which every alternate colour was a shade of red, the other two colours being green and blue.

For projecting pictures it was also suggested to dye the films corresponding to the colours of the screens through which the corresponding negatives were taken or to employ similar screens.

The invention has for its general object to provide means whereby the natural shades and tones of the subject photographed can be more nearly reproduced on projection; and the more specific object is to reduce to a minimum the "flicker" effect in colour moving picture projection.

With this end in view the invention consists in the production of a moving-picture film bearing continuing aspects of a subject in successive groups of six picture image-sections, each

section showing a colour selection and three of which being of red colour are alternately disposed in their relation to the other three picture image-sections of the group, of which only one is of green colour selection and the remaining two are of primary colour selection other than red.

The invention further consists in making a positive film from the negative, and projecting it with the aid of recurring red and green filters, the picture image-sections of red colour selection being coloured by the red colour filter and the other picture image-sections each being coloured by a green colour filter.

The invention also consists in a method for projecting moving pictures in colours in a moving picture projector without the aid of colour filters in which the picture image areas of red colour selection of the film bear a red colour tint and the other picture image areas each a green colour tint.

Analysing the problem of "flicker" common to moving

pictures in colours comparison has been made with the regular "black and white" moving pictures and seemed that the trouble could be remedied if the positive film ready for projection in colours could be made of such quality that the differently coloured separated picture-sections comprising the image should not only show a difference in the opacities of the colour separated picture-sections, thus controlling and selecting the coloured light which it permits to pass, but these opacities should be arranged and regulated to such a degree that if projected without colour filters they should show, with the exception of the red colour separated picture-sections, images closely resembling the "black and white" moving picture where the amount of "flicker" is usually at a minimum.

This theory, later found to be a fact, is based on the view that the disturbance or "flicker" which is perceived by the retina of the eye is due to violent light changes caused by quickly and successively moving these picture section opacities alternating in contrast of strong light and shadows; what in one of the positive picture image-sections is expressed as a transparent light-passing spot is an opaque light-preventing spot in the next following picture image-section.

For illustration, if we think of the spectrum as one chain of graduated colours and hues extending from one end of the spectrum to the other, as soon as we take any link out we break the continued line of the chain and certain hues or shades of colours will be missing; the gradual colour scale will be disturbed, the absorption bands will be sharply defined and a "gap" between the primary colours of the spectrum will be formed which would cause upon the retina of the eye a sensation similar to looking upon a board marked with black and white checkers, a sensation causing an immediate disturbance to the eye, and if such a sensation is continued for a length of time the eye fatigue and "flicker" increases in proportion.

A similar sensation of "gaps" is caused upon the retina when different sharp cut primary colour filters are used in form-

ing the different colour separated opacities on the film. Besides causing "flicker" these "gaps" prevent the eye from perceiving the colours in their natural shades and hues, as each missing link represents a colour shade or hue which is necessarily a part of the spectrum.

Further analysing the "gaps" it was observed that in the projection of the different primary colours, the "flicker" was mostly trying upon the eye when green or blue-green coloured light was being passed by sharply cut colour separated opacities; the red coloured light being passed by the red colour separated picture opacities did not cause much "flicker" or pulsating effect upon the eye.

From that time on efforts were directed to picture-section opacities representing separations of wave-lengths different from red, by regulating the opacities translating the photographic details from orange, green, yellow to blue shades of the subjects to such an extent that when a positive was made from a thus regulated negative film and was projected, for instance, in monochrome, say green light, a graduated scale of different hues of green colour was perceived ranging from deep green to a very light blue green shade, according to the natural colours of the subject: the green light sifting through the translucent or semi-translucent varying opacities of the picture image-sections and forming these different hues of green colour without any "gaps".

Then when the so regulated picture-image opacities were successively projected in green coloured light in combination with alternating picture-section opacities coloured in red light, not only was "flicker" materially reduced but remarkable true shades of different colour combinations very closely approaching natural colours formed by the mixture of red light alternating with different hues and delicate shades of green light filtering through the differently shaded and graduated opacities representing photographic details from orange, green, yellow to blue shades of colours of the subject or scene.

(To be continued.)

DECENNIA PRACTICA—COLOUR PHOTOGRAPHY.

Under this heading we apply to the various branches of colour photography the processes of collection and arrangement accorded to some fifty departments of ordinary photography in the "B. J." during 1916. These extracts are from issues of the "British Journal Almanac" of the years 1906 to 1915, and the present series of epitomes thus resuscitates and brings together in compact form much useful information, otherwise scattered through nearly a dozen volumes.—EDS. "Colour Photography" Supplement.

PHOTOGRAPHY IN COLOURS BY PRISMATIC DISPERSION.

(Continued from page 20.)

M. Raymond gives a much simpler method of working. To any ordinary camera is fitted a diaphragm D (Fig. 1) behind the lens O, which, though here shown as simple, can be the ordinary camera objective. T is a cross-lined screen, behind which is placed a prism, P, in front of the plate. It is obvious that we have here nothing more than the arrangement ordinarily adopted for half-tone work, with the addition of the dispersive prism. The cross-lined screen acts precisely as a series of pinholes, which form images of the diaphragm on the plate varying in size with the distances T-P and T-O. If the diaphragm is circular the images are circular (Fig. 2); if it is an elongated diaphragm the image on the plate is a line. It is obvious, then, that by varying the distance of the screen with a circular diaphragm one will obtain a stipple in which the circles touch one another (Fig. 5); or if the diaphragm is larger, then they are partially confluent (Fig. 6). If instead of a circular diaphragm an elongated rectangle or slit is used (Fig. 7), we shall obtain a series of lines, as shown in Figs. 9-14, which will vary in their nature as the distances between screen and diaphragm and screen and plate vary. In precisely the same way with a

triangular, square, or polygonal diaphragm the images will be of the same shape and separated, juxtaposed or partially superposed.

Fig. 1.

From an examination and comparison of this method with that given in the previous paper, it will be seen that all the essential elements

to give linear images exist separated by black spaces whereon are formed the spectra. For with a square diaphragm the screen plays the triple rôle of screen, ground glass, and multiple objective, replacing the second lens of the former arrangement, and all that one needs is then the prism, which forms the spectrum of each

Fig. 2.

elementary line forming the image on the plate. When this negative is developed, a positive made therefrom placed in the same apparatus will immediately give a faithful representation in colours. A three-colour linear screen, the number of lines per inch being the same, applied behind this positive, will give an effect very near the truth.

The advantages of the apparatus are:—1. The use of ordinary

Fig. 3.

apparatus without modification, and by the simple addition of a commercial cross-lined screen and the prism. 2. The employment of a commercial screen. In practice it would appear more advantageous to use those in which the opaque lines are wider than the transparent interspaces; Schulze's 60 deg. screens perfectly fulfil this requirement. 3. The use of a prism with a narrow angle,

Fig. 5.

Fig. 6.

Fig. 7.

so that there is no deformation of the image. 4. Reduction of the total cost. 5. Rapidity of exposure, this being much greater than with the original apparatus. 6. Regulation at will of the dimensions of the lines. 7. Regulation at will of the relative sizes of the spectra. 8. Utilisation, if required, of several prisms placed one on top of the other, as in Fig. 8. 9. Utilisation of the whole of the field of the lens. 10. The optical system is reduced to its simplest expression. 11. Simplification of focussing. 12. Facility with which this process may be adopted by all amateurs, thanks to

the simplicity of the process. 13. Easy application to stereoscopy.—“Phot. Rev.,” Feb. 17, 1907, p. 51; “B.J.” Colour Supplement, March 1, 1907, p. 19.

M. Poirée suggests the following method for obtaining photographs in colours by prismatic dispersion. It is based on the non-achromatism of the lenses used, and does away entirely with the use of the prism. The system is based on the fact that if the lens is fitted with a diaphragm with annular or polygonal slit, and the image to be reproduced is divided into points by a screen, each point of the screen gives at the proper focus a spectral dot, which is round or oval, according to the position of the point of the screen with regard to the principal axis of the optical system. The distance of the points of the screen being adjusted to the optical system, the elementary spectral dots given by the collection of points of the screen are contiguous, and constitute the image to be reproduced, but the colours of which are separated. This image is received on an orthochromatic plate, developed, and converted into a positive and replaced. If the screen is illuminated by white light the photographic positive is illuminated in the natural colours, or if the positive is illuminated by white light it is the screen that reproduces the coloured image.—“Bull. Soc. Fr. Franc.,” Jan. 15, 1907, p. 61; “B.J.” Colour Supplement, March 1, 1907, p. 21.

J. and E. Rheinberg have dealt exhaustively with the theory and practice of the method of producing, on one plate and at one exposure (by means of prismatic dispersion without the use of colour filters) colour photographs which may be viewed either by projection or in a viewing instrument. They demonstrated the process, as embodied in the apparatus perfected by themselves, before the Royal Photographic Society. The full text of their paper appears in the April issue of the “Photographic Journal,” and is reprinted in “B.J.” Colour Supplement, May 3, p. 19; June 7, p. 28; July 5, p. 33; and August 2, p. 38; 1912.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE BLEACH-OUT PROCESS.

To the Editors.

Gentlemen,—In your issue of June 6, 1919, p. 22 of Colour Supplement, you give such an adverse verdict on the bleach-out process that it may deter experimenters from proceeding further with the idea. While of necessity having to agree with you concerning many of the results which were obtained, still, it is a fact that with certain of the samples distributed with such generosity by Dr. Smith, colour records were made which, so far as I am aware, are unobtainable by any other process than that of Lippmann. Looking back now some twelve years, it would seem that the chief cause of the failure of the process was its being put forward as a commercial proposition before the known difficulties attending its working had been mastered. Some of your readers may remember my exhibiting a record of the solar spectrum, made by a camera exposure, at the R.P.S. exhibition in 1908. This was made on the only satisfactory paper out of several submitted, the unbleached paper being almost black, and possibly a chance approach to perfection. I have purposely not interfered with this colour record in any way, and, so far as I can judge, it is as good now as when made eleven years ago. At that time I had persuaded one or two chemical friends to investigate the problem of the relation of fugitiveness of aniline dyes to molecular constitution, but recent events put an end to most of that. Considering the wonderful success of Sir William Pope in furnishing us with the new dyes for plate sensitising, I trust our chemists will be able to solve the problem of matching three dyes to give a black mixture of sufficient sensitiveness, which will at the same time give a stable reduction product and thus enable this most attractive process to have a satisfactory trial.

SIX-COLOUR CINEMATOGRAPHY	PAGE 29	A REVIEW OF COLOUR PHOTOGRAPHY. By H. E. Rendall.....	PAGE 31
---------------------------------	---------	---	---------

SIX-COLOUR CINEMATOGRAPHY.

[An additive process of colour cinematography, similar in its general principles to Kinemacolor but differing from the latter in the sequence and selections of the colour sensations, has been patented by Mr. Joseph Shaw, 8, South Second Avenue, Mount Vernon, New York, whose specification, No. 126,220, contains the following detailed description of the process.—Eds. "Colour Photography" Supplement.]

(Continued from page 27.)

In order to register on the moving panchromatic negative film the colour selected picture-image section-opacities for the purpose above described there was used in the taking camera in front of the negative film a movable colour screen geared to travel in synchronism with the film, the screen having six openings, each filled with one colour-filter, these six colour-filters comprising three colour-filters of short wave-length and consisting of green, yellow, and blue colour respectively, and three colour-filters of a long wave-length and each consisting of a red colour only, so arranged that each of the three red colour filters alternated to form a pair with one of the three different colour-filters of the short wave-length. When thus arranged and used in combination with a panchromatic negative film these six colour-filters register lengthwise of the film picture-image section-opacities in the following order: red, green; red, yellow; red, blue; thus forming an unbroken chain of colour separations having no "gaps".

A positive is made from this negative film and although red, green, yellow, and blue colour filters were used in the taking, it is possible to project the positive with two primary colour-filters only, namely, red and green. The picture image-section of red colour selections passing red coloured light and the picture image-sections of green, yellow, and blue colour selection each passing green coloured light.

The patentee believes himself to be the first to use in taking moving pictures in colours a movable colour screen filled with six colour-filters so arranged and selected to register on the panchromatic negative film groups of six colour selected picture image-sections, three of which represent red colour value and the balance of three colour selected picture image-sections representing green, yellow, and blue values and so arranged that the picture image-sections of red colour selection are registered every other one and the picture image-sections of green, yellow, and blue colour selection are each registered once in every group of six picture image-sections, when a positive is made therefrom to project the picture image-sections of red colour

selection in a light of red colour and the picture image-sections of green, yellow, and blue colour selection each in a light of green colour.

Thus, in each group of six picture image-sections, the red images, alternating in projection with the green images, and each green image showing a different density or shade of green colour influenced by the difference in the opacities of the green, yellow and blue colour selections, form in the projection of

Fig. 1.

each group of six picture image-sections three different pairs of colour mixtures, and when overlapped in the eye of the observer by persistency of vision produce moving pictures in colours, very nearly approaching colours of nature with a minimum amount of flicker; or the positive film bearing the successive groups of six picture image-sections of colour selection can be directly tinted, dyed or toned photographically, in which case the picture image-sections of red colour selection will bear a red colour tint and the picture image-sections of green, yellow, and blue colour selection will each bear a green colour

tint, and the projection of the positive film will take place without any recurring colour filters.

It will be clear from the above that although the positive film is projected with the aid of two primary colour filters only, the projection effects a wider range of colour tints than has been possible with any other method, but by the method of taking the pictures it is claimed that it is possible to enhance still more the variety of tints in the colour combinations by utilising in projection a recurring colour screen having four openings, two of which are filled with red colour filters, each being of a different shade, for instance, pure red and orange-red; the other two openings of the screen filled with green colour filters, likewise differing in shade, a blue-green and yellow-green, and so arranged to move in relation to the film that as one picture image-section appears at the gate of the projector, one colour-filter passes in the path of the light. Thus, in one complete revolution of the colour screen four picture image-sections will have passed the gate, thus providing

means whereby the picture image-sections of red colour selection can be alternately coloured by pure red and orange-red and the images of green, yellow and blue colour selection can be coloured by alternating blue-green and yellow-green filters.

In the drawings, fig. 1 is a diagrammatic view showing a section of film and the relation of the picture image-sections to the picture-taking screen when the film is regarded as a negative and to the projection screen when the film is regarded as a positive; fig. 2 is a view showing a positive film with its picture image-sections operatively related to the colour screen used in projection; fig. 3 is a view showing a section of a negative

selection of the same wave-length, through which the picture sections 1 of the film group are exposed. The screen also has green, yellow and blue filters 2^a, 3^a, and 4^a respectively, arranged in alternate relation to the red filters. The relation of the colour filters to the picture image-sections can be traced by the connecting arrow lines 5.

In fig. 1 is shown the screen S¹, which is used in projecting

Fig. 3.

the moving picture image-sections. This screen has two filters 6 and 7 which are red and green, as designated by the letters R and G. This screen is moved in such relation to the film A, which is assumed to be a positive in this explanation of the screen S¹, that the red filter 6 will register with the successive red image-sections 1 of the film and the green filter 7 will

Fig. 4.

register alternately with the green, yellow and blue picture sections 2, 3, and 4, this relation being indicated by the arrow lines 8 and 9, respectively.

Fig. 2 shows a portion of a negative A¹ with two groups of moving picture sections, and the projecting screen S² has two groups of red and green filters designated R¹-G¹ and R²-G², respectively. The relation in which these various filters register with the image-sections of the film can be traced by the arrow lines designated respectively g¹-r¹, g²-r².

Fig. 2.

film and the relation of the picture image-sections to the picture-taking screen and the relation of the image-sections of the negative film to the tinted corresponding image-sections of the positive film and to the positive film projection screen when the film is regarded as a positive; and fig. 4 is a similar view showing a positive film in four tints.

Referring to fig. 1, A designates sufficient of a film to include a group of picture image-sections of which alternate sections 1 are red colour sections, as designated by the letter R, and the sections 2, 3 and 4 intermediate adjacent sections 1 are green, yellow, and blue colour sections, as designated by the letters G, Y, and B. Adjacent to the film, which is to be regarded as a negative, is a colour screen S which moves in synchronism with the film by any approved manner and is employed in taking of the moving pictures. This screen has three red colour filters 1^a, which are substantially of a colour

It will be clear by reference to fig. 2 that the picture image-sections of green, yellow, and blue colour selection in one group of six picture image-sections are differently affected by the G^1 and G^2 filters than they are in the next following group. In a given group, for instance, the picture image-sections of green and blue colour selection are affected by the G^2 filter and the picture image-section of yellow colour selection is affected by the G^1 filter, but in the next following group the order reverses—the picture image-sections of green and blue colour selection will be affected by the G^1 filter and the picture image-section of yellow colour selection by the G^2 filter. Also, in every group, that every other picture image-section of red colour selection is affected by the R^1 filter and the intermediate picture image-sections of red colour selection by the R^2 filter.

In further reference to the drawings, fig. 2, illustrating the projecting method with four filters, the R^1 is a pure red and the R^2 is an orange-red filter; the G^1 is a yellow-green filter and the G^2 a blue-green filter. Assuming that the screen revolves to the left, the R^1 filter will follow the G^1 and the R^2 filter will follow the G^2 , and when in combination with the differently colour-selected picture image-sections, projected at a speed of about thirty pictures per second, each two successive picture image-sections are alternately coloured by the red and green filters and are overlapped by persistency of vision, thus forming pairs, the colour combination of which are being successively varied, due to the changing relation of the different colour filters in combination with the varied colour selections of the picture image-sections, for example, as shown in the drawing, the film passing downward in a given group of six picture image-sections, beginning with a picture image-section of red colour selection and the R^2 filter, the R^2 and G^2 filters affect the picture image-sections of red and green selection, whereas in the following group of six picture image-sections the picture image-sections of red and green colour selections will be affected by the R^1 and G^1 filters; likewise, in the first group the picture image-sections of red and yellow colour selection will be affected by the R^1 and G^1 filters, whereas in the following group the picture image-sections of red and yellow colour selection will be affected by the R^2 and G^2 filters; so, also, in the first group, the picture image-sections of red and blue colour selection will be affected by the R^2 and G^2 filters, and in the following group the picture image-sections of red and blue will be affected by the R^1 and G^1 filters.

Referring to fig. 3, N designates a negative film and S a colour screen substantially the same as described in connection with fig. 1.

P designates the positive film, of which 1^p are the picture image-sections corresponding to the red section 1 of the nega-

tive film N, the gelatine of which is tinted red. The picture image-sections 2^p , 3^p and 4^p correspond respectively to the sections 2, 3 and 4 of the negative film, the gelatine of which is tinted green; with a positive thus tinted projection is made without the use of recurring colour filters.

In fig. 4 the screen S and negative film N are the same as in fig. 3, but a greater length of the negative film is shown to bring out the relation of several groups of picture image-sections in the positive film P^1 .

To effect a wider range of colour tints it is possible to enhance still more the variety of mixtures of different wave-lengths by tinting my film into two different tints of red colour and two different tints of green colour, for instance, pure red and orange red, blue-green and yellow-green, designated as R^1 — G^1 and R^2 — G^2 .

It will be clear by reference to fig. 4 that in the positive film P^1 the picture image-sections of green, yellow, and blue colour selection in the group a of six picture image-sections are differently affected by the G^1 and G^2 tints than they are in the next following group b. In a given group, for instance, the picture image-sections of green and blue colour selection are affected by the G^2 tint and the picture image-section of yellow colour selection is affected by the G^1 tint, but in the next following group the order reverses—the picture image-section of green and blue colour selection will be affected by the G^1 tint and the picture image-section of the yellow colour-selection by the G^2 tint. Also, in every group, every other picture image-section of red colour selection is affected by the R^1 tint and the intermediate picture image-sections of red colour selection by the R^2 tint.

Fig. 4 illustrates the film ready for projection in four tints. The R^1 is a pure red tint and the R^2 is an orange-red tint: the G^1 is a yellow-green tint and the G^2 is a blue-green tint, and when projected at a speed of about thirty pictures per second, the picture image-sections bearing their respective tints are overlapped by persistency of vision, thus forming pairs, the colour combinations of which are being successively varied, due to the changing relation of the different colour tints in combination with the varied colour selections of the picture image-sections. For example, as shown in the drawing, assuming the tinted film travels downwardly, beginning with the picture image-section of red colour selection bearing the R^2 tint, it will be plain that in a given group of six picture image-sections the R^2 and G^2 tints affect the picture image-sections of red and green selection, whereas in the following group of six picture image-sections the picture image-sections of red and green colour selection will be affected by the R^1 and G^1 tints, as shown in the drawing.

A REVIEW OF COLOUR PHOTOGRAPHY.

With peace almost assured in most parts of the civilised world, the enthusiast for colour photography may rightfully look forward to renewing his interest in this beautiful art, and he may be excused if he hopes that more manufacturers will devote attention to supplying his needs. Looking back through my "Colour Photography" supplements, it is perfectly plain that there has been a great falling-off of interest in this branch of photography during the last few years, if one may except a "certain liveliness" among the colour cinematograph patentees, but these hardly interest the amateur. Personally, much as we admire colour transparencies, most of us would prefer pictures to frame or paste in albums. I therefore propose to give a brief review of the various paper processes offered to the public at different times, and trust that those who have tried them will give their experi-

ences and criticise what I have written. Practically all paper processes require three superimposed prints from negatives taken through appropriate colour filters, and it is not superfluous to add that every process in colour photography requires unvarying exactness and uniformity, failing which the picture is spoilt by predominance or deficiency in one colour. Errors of exposure or printing which would be unnoticed in monochrome work may give green faces or brown grass in colour photography. I give below a list of methods for producing these record negatives, some of which I have tried.

(1) An ordinary camera, with a filter holder on the lens. In this case ordinary dark slides are used.

(2) *Repeating Back*.—This is an apparatus that fits on the back of a camera, and consists of a frame holding a long, dark slide, in front of which is a sliding filter-holder, which moves

with the dark-slide. The three exposures are made on the same plate, alongside one another.

(3) Sanger-Shepherd one-exposure camera.

(4) Hiblocks.

(5) Butler's one-exposure camera.

(6) Hamburger's one-exposure camera.

(7) Screen plate negatives.

No. 1 is quite good enough for preliminary experiments, and is not costly. Still life and copying can be done satisfactorily, but No. 2 is much more convenient to use. A repeating-back outfit is quite rapid enough for taking portraits, and, on reasonably calm days, landscapes. Curiously enough, I have never had much trouble with colour frills due to movement between exposures. First-class sets of negatives can be obtained if the following three precautions are taken: (a) Use colour filters and plates made by the same firm. (b) In selecting plates, use only those for which the makers give the factors for tricolour filters. If this is not done, a good deal of material and time has to be wasted in photographing a neutral-tinted object, adjusting the exposures till three identical negatives are obtained. This procedure is more profitable for the plate-maker than the amateur. There is at least one maker who gives these factors, and one may suppose that they are a good deal more accurate than the operator would find for himself. (c) Use an exposure meter.

No. 3.—This is a development of the three-lens camera. The three-lens camera has the obvious disadvantage that the three images can never register unless the object is a very distant one. In the Sanger-Shepherd camera one lens is used, and two big rhomboidal prisms transfer two images, one to each end of a single long plate. The centre image (red filter) passes between the edges of the prisms, which thus form a sort of square diaphragm of constant opening. A small strip only of the front face of the prisms intercepts the rays from the lens, and this strip is provided with a shutter to regulate the light passing through to each plate. This shutter is thus really an adjustable diaphragm, to be adjusted by trial and error, to allow for variation in exposure required by each filter, the red filter being the standard by which these two are set. The lens is provided with a yellow filter, in order that the diaphragm openings for all three pictures may be approximately equal in area. In actual practice I have found that when photographing near objects a uniform background must be used, as the "stereoscopic error" is quite pronounced. Sometimes I have found a difficulty in registering, even where distant objects are concerned. This I have not had satisfactorily explained. At the time the firm was busier with war work than colour photography, but on my return to England I propose to subject it to more severe tests, and write a further account of my experiences. It is fitted with a comparatively long focus lens, which makes it somewhat awkward to use at times. In rapidity it compares with an Autochrome plate. Another disadvantage is its cost—£40 for the lantern plate size (pre-war). In the above-mentioned processes the same make of plate can be used throughout, developed, and fixed for the same time, thus ensuring uniformity in the quality of the negatives.

No. 4.—I obtained some Hiblocks from America with great difficulty during the war, but I never used them in the absence of any proper holder, labour difficulties preventing me getting one made in England. A Hiblock can be used in any camera fitted with the holder, and the Hesse-Ives Co list holders for all makes of American cameras. My memory is a little treacherous as to their build up, and I am open to correction, but, as far as I remember, a Hiblock consists of the following: (a) A slow speed plate with transparent emulsion, glass to the lens. This gives the blue filter negative. (b) A celluloid film, with emulsion, strongly stained red. This gives the green filter negative. (c) A panchromatic plate, emulsion side to lens. This provides the red filter negative.

In the absence of a practical test of the Hiblock, I can hardly criticise it beyond saying that the firm issue the most complete instructions for it, and also run a department for developing and printing amateurs' exposures. I was most pleasantly impressed by the careful way all goods I received from the Hesse-Ives Corporation were packed.

No. 5.—This camera got to the practical stage by being put on the market some years ago by A. W. Penrose and Co. The camera was of the three-plate type, and provided with two transparent coloured glass reflectors. The first reflector, at 45° to the axis of the lens, reflected a proportion of the light to the blue filter plate, placed horizontally on top of the camera. This reflector was of yellowish glass, so that reflections from the back surface were cut out by the blue filter. The remaining light was partly intercepted by a transparent reflector, which served the green filter plate, placed horizontally, but on a lower level than the blue filter plate; and the red filter plate was vertical and directly in line with the lens, the light being filtered by the two reflectors which were appropriately coloured. I speak from memory when I say that the ratio of exposures was adjusted by interposing neutral tinted glasses between the plates and their source of illumination. I understand that registration was a sore point with this camera, but as I never used it, I would prefer that others gave their experience. At any rate it was far more rapid than any of the preceding apparatus.

No. 6.—This camera has the credit of being the only three-colour camera that has been successfully used in a professional studio. It has one transparent red platinised reflector that serves the blue and green record plates, placed horizontally face to face on top of the camera, and this reflector also acts as a filter for the red filter plate, placed as in the last camera vertically, facing the lens. Its special feature was a device for bending the reflector, this distortion being purposely introduced to correct any deficiency in registration. It was capable of snapshots under favourable conditions, but unfortunately was never offered for sale to the public.

No. 7.—I believe the future of colour photography lies in this direction, although Nos. 1 and 2 will always be used. I read with great interest the account of Mr. Williams' work, as I had in my mind a somewhat similar process. The Autochrome, Paget, and others have proved that it is possible to obtain three records on one plate. I think it should be possible to devise a special border pattern for the Paget screen for registering. For instance, suppose we wish to obtain a red record negative from an ordinary Paget. For this we must have a monochrome screen with opaque areas over the blue and green dots and clear glass for red dots. By photographic means it would not be hard to make such a screen, but it must have along the edges a special border of red dots so that when the screen and negative are registered a red border would appear round the negative. It is about time that some one devised a registering frame with fine screw adjustment for Paget transparencies. With such an apparatus and a magnifying glass registration should be obtained fairly easily, the two bound together with lantern-slide binding, and printed through an enlarging lantern. In a similar way blue and green negatives could be projected, blue and green borders being arranged in order that there might be no mistake. Probably a little diffusion would get rid of the grain without producing too soft a result.

H. E. RENDALL.

(To be continued.)

SOCIETY OF COLOUR PHOTOGRAPHERS.—A meeting of the committee of the society was recently held in order to consider the desirability of resuming the meetings and excursions. After some discussion it was decided to postpone calling a general meeting of the members until conditions for the practice of the more widely used colour processes have become more favourable.

Paper Printing Processes.

In dealing with methods of producing prints on paper, there is obviously no useful purpose served in referring to such obsolete processes as Pinatype, gum-bichromate, stripping films, etc., and I will limit myself to such processes as were in common use before the outbreak of war. These include the following:—

1. Carbon process.
2. Raydex.
3. Sanger-Shepherd imbibition process.
4. Micro.
5. Polychromide.
6. Bromoil transfer.
7. Bleach-out process.

Wasted time and money have taught me two lessons which I intend to follow for the rest of my photographic life: (a) Never attempt to print from any but a perfect set of negatives. In such a set neutral grey is represented by equal density in each negative. By taking trouble these are not so hard to produce as it is commonly supposed. (b) Always print a test scale together with the negatives.

Perhaps my intention in (b) is not quite clear. It is not sufficient to produce three nice-looking prints in yellow, pink, and blue, superimpose them, and expect to get a perfect result. It is an absolute *sine qua non* to know whether they are balanced. I can see only one way of guaranteeing this, and that is by constructing a kind of fraction tint actinometer to lie alongside the negative while printing. For the sake of argument we may arrange for six numbered tints, and assume that No. 4, just visible, will give neutral greys and a print of suitable density. If No. 3 is only visible in the blue and No. 5 in the red, we shall know that although the three pictures independently look all right, they will not combine, and we should be able to know from previous experiments how much more we have to expose the blue and diminish the printing time for the red picture. Whether we use 3, 4, or 5 as the average tint, of course, depends on the density of the negatives. Some such system is applicable to all three-colour printing processes, and as far as I can remember is included in the Micro process. However, I will now pass on to a short criticism of the processes enumerated above.

1. The double transfer process is, of course, used, and the best temporary support is celluloid. No one of average ability

ever has any difficulty in stripping and registering the three prints. I prefer white opal for developing the yellow picture on. The chief difficulty in the process is that each tissue requires a different time of exposure, and in a varying light this is difficult to gauge. Some workers even go so far as to recommend different strength sensitizing baths for each colour. I suggest printing not less than a dozen sets at a time, and choosing by trial the best three for any particular print. The process could be simplified by using a steady artificial light.

2. This is a form of Ozobrome worked out with great attention to detail by the Raydex Company, who supply all materials. Before going any further I think it will not be out of place to mention that they have managed to keep their flag flying during the war, and have never been too busy to give enquirers every help in working their process. The colour picture is obtained from carbon tissue, but instead of exposing this to light, it is "sensitized" by two solutions and squeegeed to a bromide print. The carbon print is the result of chemical action between the print and the tissue. With three good bromides to start with, this is a more accurate means of obtaining a print than exposing tissue in the ordinary way. The company have also obtained prints from P.O.P. which will still more simplify the process. I am sure readers of the "E.J." will await with interest further developments of this process, which should be easy and certain; but I must confess that I have found it a bit capricious. Possibly this may be due to the fact that I have only worked it in the narrow space of a ship's cabin, and with insufficient facilities for a proper washing in between the various operations. In both this and the carbon process, a colour that is deficient may be intensified by bathing in an appropriate aniline dye.

3. I have never seen more beautiful or perfect results than those obtained by this method, and every time I see them I always feel that any expenditure of time and money is justifiable to obtain the skill requisite to produce similar results. Print plates are first made from celluloid films sensitized in bichromate. These are printed in daylight, celluloid side to the negative, and then developed in warm water, which gives a positive image in silver bromide. This is dissolved out by hypo, followed by a thorough washing. It is then best to allow the films to dry. When dry they are placed in pink, yellow, and blue baths, from time to time they are rinsed, and roughly registered until a correct balance of colour is obtained. The first print plate, preferably pink or blue, is squeegeed to a piece

of gelatine-coated paper, well soaked, which absorbs all the dye, and this is then followed by the remaining two plates.

4. This process is very similar to the above, except that the films are supplied ready sensitized and varnished to protect them. In this way they will keep good for three months or so. Before development this varnish is removed by petrol or benzene. There is no difficulty in this, as any varnish not removed shows up as soon as the film is put in the water, and can at once be wiped off with cotton-wool and petrol. It is cleared with hypo, washed and dyed as in the Sanger-Shepherd process. The films, however, are not used as print plates, but are registered and sealed together over a piece of gelatine-coated paper by amyloacetate.

5. This process has never been on the market. It was used by the Dover Street Studios, in conjunction with their special camera, for professional work. The base is a bromide print toned to beautiful chrome yellow. To this a blue-toned bromide print is transferred, and the final red print is made from a specially transparent carbon tissue.

6. I confess to never having seen a three-colour Bromoil transfer, but it is fair criticism to say that it does not lend itself to such accurate work as the foregoing processes, but where the operator is an artist, no doubt, satisfactory pictures are obtained, or, at any rate, pictures satisfactory to those who admire this process. A recent issue of the "B.J." gave a description of a similar process, "Wartype," which approximates to collotype. Owing to opacity of the inks used "overlapping error" is sure to be prominent. Overlapping error is the error caused by the lower layers of colour being unable to exert their full influence due to the opacity of the upper layer, which gives a predominating tint. I think it will soon be hard to know where Bromoil transfer ends and collotype begins.

7. This is a process which was beginning to go ahead when war broke out. Its principal exponent was Dr. Smith, the inventor of "Uto" paper. Unfortunately, he has died during the war. Uto paper was coated with a film containing dyes of the three primary colours, mixed together until a black or dark olive-green film was obtained. The paper was placed under a colour transparency, and under the action of light began to bleach in the light parts. By the well-known law of light, that a coloured substance is only affected by those rays which it absorbs, the blue and yellow dyes (forming green) began to fade away under a red area, leaving the red dye untouched; and in a similar way under all coloured areas, the dyes of a complementary colour faded, leaving a positive image of correct colouring, or at any rate this was the theory. However, I fear the number of spoilt Autochromes exceeded the number of good prints produced. The fugitiveness of the dyes was increased by "sensitizers" such as anethol or thiosinamine. The prints were fixed by dissolving out the sensitizers, and I presume there was something else in the bath to increase the stability of the dyes. If a print had a tendency to go pink during printing, green glasses were supplied to place over the whole until things went right. As the process has been slowly developing for at least fourteen years, perhaps it may ultimately be satisfactory. Another variation of this process has not yet had much of a trial, and that is to bleach out each colour independently. Thus we might have blue, pink and yellow tissues on thin waxed celluloid bases. Bleach each out under a monochrome positive, using an actinometer scale with each print, and then transfer them in succession to a paper base.

"Of the making of many books there is no end," says the Prophet, and the same might be written about processes in colour photography; and if an excuse is required for describing a process which I have never actually put into practice, it is because I have evolved it after many years' experience. I do not claim anything new or revolutionary for it, but I think that amateurs should be most successful with it. I expect it has been used many times, in fact, I know it has, but I in-

tend to use it in the future. Briefly, the outline of it is as follows: The red-filter negative is hardened and given two or three coats of celluloid varnish. The base of the colour print is a bromide print toned blue. This has to be well soaked in water before using, otherwise it will be impossible to register the other two components. At the bottom of the print, space is found for the actinometer scale, which should include at least three tones. The yellow and pink prints are formed from carbon tissue, which is made up with a small proportion of silver bromide instead of pigment. This is treated in the same way as an ordinary double-transfer carbon print, using celluloid as the temporary support. These two prints are washed, cleared and dyed as for the Sanger-Shepherd process, but the pink print carries its scale at the bottom of the picture, and the yellow at the top. When judged correct the pink print can have its scale registered with the blue, and the yellow on top. The two scales being at opposite ends, the yellow picture is clear of the back of the pink, so that there is no danger of it being scratched. I have found that there is no danger of the pink dye transferring to the bromide print in the short time necessary for testing. With the number of different brands of bromide paper on the market I do not think it would be hard to find one with the same scale of gradations as the gelatine-dye picture. Of course, the blue picture could be made in the same way as the pink and yellow, but in this case a special baryta-coated transfer paper would have to be used, otherwise the dye would diffuse into the pores of the paper and give a blurred print.

H. E. RENDALL.

THE LABORATORY PREPARATION OF THE COLOUR-SENSITISING DYES, PINAVERDOL AND PINACYANOL.

A CONTRIBUTION from the Colour Laboratory of the United States Bureau of Chemistry, which is reprinted below, describes in detail the chemical preparation of the two dyes, pinaverdol and pinacyanol, which are chiefly used in the preparation of orthochromatic and panchromatic plates. The methods worked out for the preparation of the intermediates used in the making of these dyes—namely, the quinoline bases and the quaternary halides—have been the subjects of separate communications, copies of which are available from the Colour Laboratory, Bureau of Chemistry, United States Department of Agriculture, Washington, D.C.—Eds. "B.J."

The photo-sensitising dyes that have gained the ascendancy in panchromatic plate manufacture are two derivatives of quinoline, termed "pinaverdol" and "pinacyanol" by the German dye manufacturers. Since 1916 these dyes have also been produced by British manufacturing chemists under the names "sensitol green" and "sensitol red" respectively. We have made more than fifteen dyes of this general type¹. A study of their absorption spectra, together with the results of photo-sensitising experiments carried out under the direction of Drs. Merrill and Burns, of the Bureau of Standards, and by Mr. H. A. Piper, of the Chemical Section of the Science and Research Department of Aircraft Production, has shown the identity with the above-named German and British products of two of our dyes, which we have termed respectively "Pv. I." and "Pc. IX."

Pinaverdol is prepared from a mixture of the methiodides² of toluquinaldine and quinoline by the action of alkali and air. The probable constitution³ is best represented by the formula:

¹ The work on photography formerly carried on in connection with the Chemical Section of the Science and Research Department of the Bureau of Aircraft Production is now being completed by the Colour Laboratory, Bureau of Chemistry, Washington, D.C.

² Wise and Adams, *Journal of Industrial and Engineering Chemistry*, 10 (1918), 801.

³ The mechanism of the formation of these dyes has been discussed in an earlier communication from this Laboratory (Wise and Adams, *Loc. cit.*).

Pinacyanol is prepared from a mixture of the ethioidides² of quinaldine and quinoline, by the action of formaldehyde and alkali. The constitution of this dye is still in doubt, but from present indications it is problematical whether the quinoline ethioidide actually enters into the reaction. If it does not, the formula³ of the dye becomes :

When pinacyanol is treated with an excess of silver chloride under proper conditions, it is quantitatively converted into the corresponding chloride (Pc. XII.). The greater solubility of the chloride renders it more suitable than pinacyanol (iodide) for use in bathing plates.

In the synthesis of these dyes we have been guided largely by the German patents⁴, which give good descriptions of the methods of preparation, but which fail to emphasise a few necessary precautions. The details of our own procedure for the preparation of Pv. I. and Pc. IX. and XII. are given in the following experimental part :—

Pv. I. (PINAVERDOL OR SENSITOL GREEN).—Fourteen grains of *p*-toluquinaldine methiodide and 25.8 gms. of anhydrous quinoline methiodide are dissolved in 400 ccs. 95 per cent. alcohol. The solution is heated to boiling and 77 ccs. of 0.7 *N* alcoholic potassium hydroxide (= 3.0 g. of potassium hydroxide) are gradually added from a burette. The mixture is maintained at its boiling point for 5 minutes after the addition of the alkali is complete. Fifty ccs. of alcohol are then added, and the crimson-coloured solution is permitted to cool slowly. A blue-black, granular, crystalline mass is deposited. The crystals are filtered and dried. The weight of the crude dye is about 5.5 gms. (about 25 per cent. of the theoretical). The product is pulverised, the powder introduced into an extraction thimble and extracted with ether in a Soxhlet apparatus, until the extract is no longer coloured. Ether removes an unidentified yellow substance. The extraction is then repeated, using absolute methyl alcohol, until the extract shows but a slight pink colouration. Ordinarily a brick-red powder remains in the extraction thimble.

The combined methyl alcohol extracts are then concentrated gradually, and the warm saturated solution is seeded with a few crystals of pure pinaverdol. On very slow cooling, Pv. I. crystallizes in beautiful, metallic needles resembling brass splinters. If the solution contains impurities, is concentrated too far, or is cooled too rapidly, the dye shows a tendency to crystallize out suddenly in fine, blue-black needles. In this form the dye is less pure than that obtained on slow crystallization.

The yields of pure dye are invariably low, the highest yield being about 3 gms. (13 to 14 per cent. of the theoretical amount).

Calculated for $C_{22}H_{21}N_2I$: I = 28.9 per cent. Found : I = 28.95 per cent., 28.95 per cent., 29.04 per cent.

The foregoing procedure presents only a slight modification of that outlined in the German patent⁴.

The following method for the preparation of Pv. I. is still more convenient, in that it yields a pure product without the tedious extraction with ether and methyl alcohol :—

Fourteen grams of the toluquinaldine methiodide and 25.8 gms. of quinoline methiodide (anhydrous) are dissolved in 400 ccs. hot absolute methyl alcohol. The solution is heated to boiling in a beaker and 90 ccs. of 0.53 *N* solution of sodium methylate in methyl alcohol are very gradually added to the mixture, which is then slowly evaporated to about 4/5 of its initial volume. The hot solution is then transferred to an Erlenmeyer flask and seeded with a few crystals of pure Pv. I. The flask is then loosely stoppered and the solution permitted to cool very gradually. Within 24 hours the bottom of the flask becomes coated with the characteristic brassy crystals of Pv. I., from which the mother liquor may be decanted. The crystals can be freed from the adhering solution by washing first with methyl alcohol-ether mixtures, and finally with ether

alone. Further concentration of the mother liquors may yield additional small amounts of Pv. I. The total yield is about 12 per cent. of the calculated amount. Spectrometer readings show that the product obtained by this method is identical with the German pinaverdol, and a colorimetric comparison of the alcoholic solution of both the German pinaverdol and our product indicates that the dyes are of the same order of purity.

The following data are taken from the detailed account of the crystallographic and optical properties of Pv. I., published by Dr. Edgar T. Wherry⁵ :—

Crystal system : monoclinic, $a : b : c = 1.1014 : -1 : 1.6053$, $\beta = 88^\circ 20'$. Habit : (see Fig. 1) usually prismatic unit prism and small clinopinacoid, terminated by large faces of the two orthodomes ;

Fig. 1. Crystal form of Pv. I; *m* = unit prism (110); *b* = clinopinacoid (010); *d* = + orthodome (101); *D* = - orthodome (101); *c* = base (001); *U* = - unit pyramid (111).

frequently showing small faces of the base, negative unit pyramid and unit clinodome; and occasionally other forms.

Metallic reflection : from faces in the prism zone, brass-yellow; from unit domes and pyramids, beetle-green; from base and faces adjacent to it, bronze-violet.

Optical properties : transparent for white light only in very thin crystals, but red light is transmitted by thicker ones. (For study by the immersion method aqueous liquids must be used.) Refractive indices only roughly determinable; for $\lambda = 0.625$, $n = 1.6$, and $\gamma = 1.8$. Extinction, in the acute angle β , 5° . Pleochroism strong, violet-brown to deep greenish brown.

Pc. IX. (PINACYANOL OR SENSITOL RED).—A solution of 90 gms. of quinaldine ethioidide and 85.5 gms. of quinoline ethioidide in 3,000 ccs. of 95 per cent. alcohol is heated to boiling under a reflux condenser in a large, round-bottom flask. When the air in the flask has been completely displaced by alcohol vapour, a freshly prepared mixture of 90 ccs. of 16 per cent. (aqueous) sodium hydroxide solution and 60 ccs. of formaline solution (40 per cent. formaldehyde) is poured through the condenser into the flask, care being taken not to chill the reaction mixture far below its boiling point. After the addition, the colour of the alcoholic solution changes rapidly from yellow to purplish blue. Six hundred ccs. of hot water are then added to the mixture, which is rapidly heated to boiling, and maintained at its boiling point for about 15 minutes. On slow cooling, a mass of lustrous blue-green needles is deposited from the solution. The product is filtered on a Buchner funnel and washed with small successive portions of ice-cold alcohol, and finally with ether. Since further concentration of the mother liquor is unprofitable, the dark red filtrate is discarded. The yields of dye obtained by the above method vary from 23 to 27 gms.

Calculated for $C_{23}H_{27}N_2I$: I = 26.35 per cent.

Calculated for $C_{21}H_{23}N_2I$: I = 27.14 per cent.

Found : I = 26.27 per cent., 26.55 per cent.

Found in a sample of British sensitol red : I = 26.7 per cent.

The product is fairly soluble in hot alcohol, yielding a purplish blue solution. It is very nearly insoluble in water.

From absorption data and the results of photo-sensitization experiments, further purification of the dye appears to be unnecessary. Absorption curves indicate that our dye is identical with samples of the German (Hoechst) and the British (Ilford) product.

The above procedure for the syntheses of Pc. IX. is very satisfactory. The only precaution that need be emphasised is that an

⁴ Pinaverdol, D. R. P. No. 167,159, Example 1 (1903); Pinacyanol, D. R. P. No. 172,118, Example 1 (1905).

⁵ J. Wash. Acad. Sci.

should be excluded (as far as possible) from the alcoholic solution of the ethiodides prior to the addition of the alkaline formaldehyde solution. Air, in the presence of alkali, causes the formation of red isocyanine dyes, which undoubtedly appear in the mother liquors from Pc. IX.

Although quinoline ethiodide is one of the re-agents used in the above procedure, we have no direct evidence that it is involved in the reaction forming the dye. When this quaternary halide is omitted from the reaction mixture, and a corresponding weight of potassium iodide added, a dye which we have termed Pc. X is formed. This dye resembles Pc. IX. very closely, and may be identical with it. In this case, however, the crude product requires further purification, and the yield is disappointing.

Pc. X. is prepared as follows: A solution of 90 gms. quinaldine ethiodide in 3,000 ccs. of alcohol is heated to boiling under a reflux condenser. Precautions are taken to exclude air. A mixture of 52 ccs. of 15 per cent. sodium hydroxide solution (= $\text{O} = 45$ ccs. of 16 per cent. sodium hydroxide solution) and 60 ccs. of 40 per cent. formaldehyde solution is then run into the boiling mixture, to which is subsequently added 600 ccs. of an aqueous 10 per cent. potassium iodide solution. The mixture is then boiled for about 20 minutes. On cooling, 21 gms. of a greenish black crystalline product is obtained, which, after two recrystallizations from 70 per cent. alcohol (containing small amounts of potassium iodide), is obtained in the form of shimmering, green needles. The yield is about 8 gms.

Calculated for $\text{C}_{23}\text{H}_{27}\text{N}_2\text{I}$: I = 26.35 per cent. Found: I = 26.84 per cent.

Whether or not Pc. X. is identical with Pc. IX. is still undetermined. Its absorption spectrum is certainly very nearly identical with that of Pc. IX., and its sensitising power is practically the same as that of Pc. IX.

Pc. XII. (CHLORIDE CORRESPONDING TO PINACYANOL).—Pc. IX. may be quantitatively converted into the corresponding chloride (Pc. XII.) by the following treatment:—2.41 gms. (1/200 mole) of Pc. IX. are dissolved in 25 ccs. of cold concentrated hydrochloric acid, and the solution is slowly poured into an Erlenmeyer flask containing 2.2 gms. of freshly-prepared silver chloride suspended in 25 ccs. of concentrated hydrochloric acid. The mixture is shaken thoroughly for several minutes, after which four to five volumes of water are added. The solution turns blue, and a finely divided precipitate of silver chloride is formed. The latter is filtered off, and the filtrate rendered very faintly alkaline with aqueous potassium hydroxide. The treatment precipitates the dye (Pc. XII.) in the form of dark blue sludge. The product is washed with water on the centrifuge until the washings are neutral to litmus, and is then filtered. Without separating it from the filter paper, the crude dye is transferred to a 300 ccs. flask and extracted (under a reflux condenser) with 150 ccs. of 80 per cent. ethyl alcohol. The hot alcoholic solution is filtered, and on cooling very slowly the dye crystallizes in the form of flat, blue-green needles, which show a tendency to mat together. Careful concentration of the mother liquor yields two additional crops of the chloride. The total yield of the dye is about 1.8 gm.

Calculated for $\text{C}_{23}\text{H}_{27}\text{N}_2\text{Cl}$: Cl = 9.07 per cent. Found: Cl = 8.33 per cent.

Both analysis and absorption data indicate that the compound contains water of hydration or alcohol of crystallization, but this point has not been settled.

Reports from the Bureau of Standards and from the Ansco Research Laboratories indicate that the chloride (Pc. XII.), because of its solubility, possesses marked practical advantages as a photosensitizer over the corresponding iodide (Pc. IX.).

ABSORPTION SPECTRA.—The spectro-photometric measurements were made with a König, Martens, and Grünbaum spectro-photometer. The dyes were studied in 95 per cent. alcohol solution in a cell 1 cm. thick against a similar cell containing solvent alone. The concentrations of solution used were 0.01 gm. per litre, or 0.005 gm. per litre, according to the maximum absorbing power of the substance.

THE BUTLER THREE-COLOUR CAMERA.

To the Editors.

Gentlemen,—I note in reading Lieut. H. E. Rendall's "Review of Colour Photography" in the "B.J." of August 1, in making reference to No. 5 camera of the series—viz., Butler's one-exposure tricolour camera—that he was given to understand registration was a sort point with this camera.

May I assure him that it was, but it was my difficulty, not the users' of the cameras. It was a difficulty which I successfully overcame years ago in the work of its adjustment.

Numerous prints have been made showing no lack of register even when enlarged three or four diameters from the negatives taken by my camera, which I should be pleased to show to Lieut. Rendall if expedient.

Herewith I enclose two samples of three-colour block enlargements from my camera negatives. With regard to the speed, I took several sets of landscape negatives recently, using Ilford's Special Rapid Panchromatic plates, and secured fully exposed good results by $\frac{1}{2}$ sec. exposures. For copies of oil paintings, etc., by interior light, the exposures extended to 2 mins.

The belief that Lieut. Rendall would welcome the correction of a mistaken impression, is my apology for troubling you with this letter.—I am, dear Sirs, yours faithfully,

EDWIN T. BUTLER.

26, Craven Park, Willesden, N.W.10, Augus 29.

[The proofs sent by Mr. Butler, one of which is a leafless tree subject, show excellent registration. We understand they represent three or four times enlargement of the original negatives.—Eds. "Colour Photography" Supplement.]

IS THREE-COLOUR A BLIND ALLEY?

To the Editors.

Gentlemen,—I am sure we are all indebted to Mr. Rendall for his review of colour-photography, and share his regret that we cannot yet show good prints on paper.

But I should like to warn beginners against taking up the work just where it was left when the war broke out; if we are beginning afresh, let it be really a fresh start.

It is quite a false assumption to think that, having got three-perfect colour-selection negatives, it is only necessary to choose a good colour-printing process, superimpose the three images, and the thing is done, and that all further trouble is the fault of the printing process.

It is not so. Rather it is we who are imposed upon; for in Nature the colour, however tertiary, is reflected, atom by atom, direct to the eye.

No matter how pure the colour or dye employed, there is always a certain amount of opacity in the three superimposed images, and if they are placed in order—yellow, red, blue—then the rays or pencils of light have to pierce the blue and red to reach the yellow, and, reflecting back from the paper, struggle once more through the intervening images to bring the yellow colour to the eye.

When—throwing theory overboard—we reduce the red and blue images, a lot of fine detail is lost; we may have got some sort of balance, but the result is like nothing in Nature. The natural colour photograph must be composed as one homogeneous whole if it is to be really natural.

Therefore, I propose that we cut the losses of the years spent in trying these "indirect" methods, and return to the "direct."

About 1870, Poitevin and several German experimental workers had got results of some sort by direct means, and probably dropped further work in that direction when the three selective colour, or "indirect," method came in and promised to be such a success.

A short résumé of where we stand in "direct" methods should be very helpful just now, when it seems easier to keep on in the old way, which I feel convinced is a "blind alley."—Yours faithfully,

S. G. YERBURY.

A SIMPLIFIED METHOD OF DEVELOPING AUTOCHROME PLATES. By A. and L. Lumiere and A. Seyewetz	PAGE 37	TWO-COLOUR PRINTS OR FILMS BY COPPER AND IRON TONING	PAGE 38
		CORRESPONDENCE: Three-Colour Photography.....	39

A SIMPLIFIED METHOD OF DEVELOPING AUTOCHROME PLATES.

SOME years ago we published a method of developing Autochrome plates, according to which the observation of the time required for the appearance of the first outlines of the image in a suitably diluted developer served as an indication of the correctness of the exposure of the plate, or whether it had been over-exposed or under-exposed, and also enabled the user to determine the time during which the plate should be developed in a solution to which an addition of concentrated developer had been made in order to obtain a good result.

This variable time of development, which is determined by the time of appearance of the first outlines of the image, is given in a table which we worked out by a series of practical tests made on plates which had received various degrees of exposure—under, over, and correct.

The method yields very good results, and allows of a very satisfactory transparency being obtained with a plate which has been exposed as much as four times the normal time. In use, however, it has the disadvantage of requiring the table of figures, prepared as a transparency, to be read by the dull light of the dark-room, a condition which is liable to give rise to mistakes.

An amateur worker, M. Meugniot, has communicated to us a method of working which is simpler than that we had indicated. It consists in bringing up the first outlines of the image always in a dilute developer, but this dilution is so adjusted that, in subsequently continuing development in a more concentrated developer, the times of immersion in these two successive developers shall be equal. We have adjusted the degree of dilution of the developers to be employed according to this new system, so that exactly the same quantity of developer is used as in the former method.

The system of working which gives the best results is as follows:—

Developing solutions. The stock solution is that which has hitherto been used—viz. :—

Metoquinone	15 gms.
Soda sulphite, anhydrous	100 gms.
Potassium bromide	6 gms.
Ammonia, 22 deg. B (sp. gr. .923)	32 ccs.
Water	1,000 ccs.

For a 9 x 12 cm. plate in a 9 x 12 dish two solutions are made up from this stock solution:—

Solution A.	
Stock solution	10 ccs.
Water	15 ccs.
Solution B.	
Solution A	2 ccs.
Water	30 ccs.

The plate is immersed in the B solution, observing all the necessary precautions for the development of the Autochrome plate.

The time of appearance, from the moment of immersing the plate in the developer, of the first outlines of the image, not reckoning the sky, is noted either with a stop-watch or a sand-glass.

As soon as the first outlines of the image appear, solution B is poured off and replaced by the portion left of solution A—namely, 23ccs. Development is then done for exactly the same length of time as was required for the image to appear in the first developing solution.

When using a sand-glass, it is sufficient, as soon as the first outlines of the image have appeared, to stop the passage of the sand by laying the glass in a horizontal position and then placing it vertical again, but the other way up, in front of the dark-room lamp. In this way the sand-glass indicates a second period of time exactly equal to the first.

The remaining operations, reversal and re-development, are done in the usual way.

We have developed by this method a number of Autochrome plates which have received exposures ranging from one to four times that of correct exposure, and have obtained in all cases as good results as by our former method.

This new system of development appears worthy of being brought to the notice of Autochrome workers on account of its great simplicity and the excellent results which it yields.

A. AND L. LUMIERE.
A. SEYEWETZ.

TWO-COLOUR PRINTS OR FILMS BY COPPER AND IRON TONING.

[Details are given in a recent patent specification, No. 119,854, of a method of producing two-colour prints or films worked out by Mr. F. E. Ives, in which the essential feature is the combination of a red copper-toned silver image with a blue-green image, the latter preferably formed by toning with iron salts. The specific claims made in respect to the process and product are given in "Patent News" on another page.—Eds. "Colour Photography" Supplement.]

THE object of the invention is to afford a simple, effective, and convenient mode of producing a multicolour picture or print, and one which, compared with hitherto known processes, will be less complicated and quicker to carry out, and will yield a better product, having superior and more permanent colouring. It relates particularly to the known type of process in which at least two differently coloured images are successively produced in or on the same carrier, whereby the necessity of attaching independently produced supports is obviated. The invention could, for instance, be applied to the production of the images at the opposite exterior faces of the support, which may be of gelatine or other colloid, with preferably a celluloid core or base between the exterior faces; but it has the advantage of being equally applicable to the production of the images within, and at different surfaces, of a single colloid layer at one side of a transparent or celluloid carrier. As the product has one face free from any image-carrying layer, the method of production last referred to is peculiarly adaptable for use in the production of a colour motion picture film free from liability to injurious defacement of the pictures.

For the purpose of describing one embodiment of the invention it is assumed that two or more simultaneously exposed views or series of views have already been taken from substantially a single view-point for securing colour-selection negatives from which afterwards the positives or diapositives are to be made. The two-colour system is supposed to be employed, for, although the three-colour system might be used, the two-colour is eminently more simple and is sufficiently satisfactory for general practical purposes.

In exposing for taking the view or series of views, a red screen may be interposed in the path of the light-rays, or in some other way a selection of the red rays may be made, and in connection therewith a film sensitised specially for red rays may be employed. Thus red-selection negatives are obtained. Similarly a green screen and green-sensitive film may be employed for securing green-selection negatives.

It has been proposed to produce in a single gelatine layer an insoluble colour image such as a silver image toned by well-known methods, or an iron-blue image, and subsequently to add a second image of a different colour, either consisting of a soluble dye introduced into the gelatine layer by absorption, or produced by sensitisation of the image-containing layer with iron salts, printing, and developing. The present invention constitutes an improvement on this method and eliminates disadvantages in production, and defects in the product, by applying a particular treatment, not heretofore adopted in this connection, for the toned silver print and by employing this particular treatment in connection with the location of the two images in or on different surfaces of the same carrier. Such location *per se* is, however, already known, it having been proposed to produce a toned silver image by exposing a sensitive layer from one side and to produce in the same layer a dye image from a silver image made by exposing the layer from the opposite side without resensitising.

The invention, in its application to the two-colour system, may conveniently be carried out in the following manner. Assuming that the negative 10 represents the green components of the picture, and the negative 11 the red components, eventually the final picture will include a blue or green positive image

from the red-representing negative, and a red positive image from the green-representing negative.

One of the two negatives 10 or 11 is preferably a reversed negative; for example, the green-representing negative 10, which may be used for rear exposure through the carrier of the print, as is hereinafter described.

The print or film 12, in which the positive images are to be formed and blended, comprises a colloid portion or layer 13, supported on a transparent or celluloid carrier 14. The carrier

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

14 may have a colloid layer 13 on each side, but it suffices to employ a single colloid layer on one side thereof, since in the preferred embodiment both of the positive images are formed in the single layer.

The first step in the process is to expose by means of one of the negatives, and form an image at one surface of the colloid portion of the print or film 12. It is to be assumed that the colloid layer 13 is sensitised with silver haloid. The first printing is preferably by the green-representing negative 10, and, as shown in Fig. 4, this negative is used to effect the exposure at the rear or through the carrier 14, so that the resulting image will be confined largely to that side of the

gelatine layer which is next to its carrier, and may be referred to as the bottom or interior surface. The negative 10 will preferably be a reversed negative, as before stated.

The procedure of making the first or silver image might in some cases be reversed by making it at the exterior or top surface of the gelatine, and subsequently making the complementary image at the interior surface; but the first-mentioned procedure is better, simpler, and is the preferred embodiment.

Having been exposed, the silver image may be developed, and will be found confined to the interior surface of the gelatine in manner that will be roughly understood from the enlarged cross-section Fig. 5, in which the colloid layer 13 is shown as having the silver image 15 at its bottom side with a mass of clear gelatine 16 extending between the image and the top surface.

This silver or bottom image, it will be understood, is a black and clear image, but according to the invention it is subsequently colour-toned, preferably to a red colour. This colour-toning may be performed subsequently to the exposure and printing for the second or blue-to-green image, although, as described, the exposure for the red or bottom image is performed prior to the exposure for the blue-to-green or top image.

After the silver image 15 is developed, the gelatine layer may be easily re-sensitised for exposure at its exterior surface. A convenient mode for producing the blue-to-green image is the iron process. The colloid layer may be subjected to a 2 per cent. bath of green citrate of iron and ammonia with an immersion of about five minutes, followed by blotting off and drying.

The top or exterior surface of the gelatine may now be printed by means of the red-representing negative 11, which, of course, is to be accurately registered with the silver image already formed. This printing step is indicated in Fig. 6. After exposure the iron-salt print is converted into a cyanotype blue-print by development with a 1 per cent. solution of potassium ferricyanide applied for about ten seconds, and then immediately washed out again.

There is now an insoluble silver image at one side and an insoluble blue-to-green image at the opposite side of the colloid layer 13. The latter may be described as a pigment image to distinguish it from a water soluble dye, the former being insoluble and not liable to wash out in subsequent steps.

The silver image is next converted into an insoluble or pigment image of red colour by the following means. The image is first converted into copper ferrocyanide by soaking in a copper toning bath for a period of from fifteen to sixty minutes, this bath being prepared as needed, by mixing equal parts of the two following stock solutions A and B:—

A	Copper sulphate	7 gms.
	Potassium citrate	28 gms.
	Water	1,000 c.c.s.
B	Potassium ferricyanide	6 gms.
	Potassium citrate	28 gms.
	Water	1,000 c.c.s.

This converted image may be fixed in a bath of hypo, which leaves a transparent copper red image, which, with the therewith blended cyanotype blue-print, gives approximately what is required under the two-colour process; but the fixing out in hypo may sometimes be advantageously omitted.

The blue-to-green or exterior image is indicated at 17 in Fig. 7, it being for the most part completely separated from the interior image 15 by the clear gelatine 16, but possibly, owing to extreme depth of both images at one point, the two may overlap, as indicated at 18, without, however, any material effect upon the process or product.

An important advantage of the invention is its flexibility, permitting a considerable latitude of modification of colour components. A satisfactory print is obtainable when the silver image is copper-toned prior to the iron sensitization for the cyanotype print. With this process the blue print can be modified to a greener hue by treatment with extremely dilute

potassium bichromate solution rendered slightly acid with sulphuric acid; while, if considered necessary, the copper red print also can then be intensified or modified in hue by mordant dyeing. While a third colour could be added as heretofore proposed, the complications attendant on this render the two-colour system commercially important, notwithstanding that the exhibited colours will be only approximately accurate representations of the original. It is this approximation of colour, and additionally the desire of the motion picture artist to secure certain colour tones or effects, which render the flexibility of the process and adaptability to colour modification important for the purposes of the invention.

While it is preferred not to place the two images at opposite sides of the celluloid carrier, this if done would be performed, as previously described, by first producing the red print in the colloid at one side through exposure for the silver image and subsequent copper toning, and at the opposite side sensitising the other colloid coating and exposing for the blue-to-green image after the exposure of the silver salt.

The product of this invention in its preferred form is a colour photograph or film comprising colloid material containing a red copper toned silver image blended with a blue-to-green image; the two images being in different portions of the colloid, preferably at opposite sides of a single layer.

In the Fig. 8 modification where the colloid consists of two layers 13a and 13b on either side of the core or carrier 14, the first exposed and developed image 15 will be understood to be the silver image which is to be converted to a red colour, located in the colloid layer say 13b, while the subsequently exposed image 17, which may be a cyanotype print, is in the opposite colloid layer say 13a.

THREE-COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—Mr. S. G. Yerbury's able letter and query, "Is Three-Colour a Blind Alley?" in the "B.J." of September 5, concerning Lieut. H. E. Rendall's "Review of Colour Photography" in the "B.J." of August 1 and September 5, claims the attention of many earnest workers interested in the evolution of colour photography, particularly now that the war is at an end, with opportunities of progress again possible.

Many experts will quite agree with Mr. Yerbury that now is the time to make "a really fresh start" in colour photography. Surely all experienced workers in tri-colour must now conclude something is radically wrong with the whole subject, as promoted commercially by various scientists during the past few years. Negatives have to be faked, fine-etching employed upon half-tone blocks, and, generally, printing in colour photography seems almost a farce, by reason of so much hand work and artifice being necessary before even fairly good colour prints by photographic means can be produced. These scientists generally trace the cause of failure in photographic colour printing to imperfections in the printing inks employed; but this assertion almost appears a libel upon the ink manufacturers if we consider the beautiful colour prints produced in the past by chromo lithography, twelve to twenty various coloured ink impressions being superimposed in printing with marked success.

Yes, a really fresh start is now necessary. But this new departure must be made by amending past proved errors, and supplementing tri-colour photography, not by "scrapping" the whole subject as "a blind alley," according to the conviction of Mr. Yerbury.

In the first place, a return must be made to the first principles

of colour, particularly in the making of colour filters, as realised by artists since the Renaissance, and as so accurately described by Ducos du Hauron (the inventor of tri-colour photography) in his master patent specification No. 2975, of 1876. There he states: "I obtain separately in the camera three impressions, three negatives of the same subject, furnished by three different lights—green light, orange light, and violet light. I make the red monochrome under the negative which is given by the green light, the monochrome blue under the negative given by the orange light, the monochrome yellow under the negative from the violet light. The superposition of the three monochromes, adapted mechanically the one to the other and placed on a white ground, produce the composition, the polychromatic image, desired."

N.B.—In this specification the lights, or filters, are the secondary colours—green, orange, and violet—of the artist, and are complementary to the three primary colours—red, blue, and yellow—which all experts now know in hue as necessary for producing all other colours in printing, with one exception. This exception is a vivid green, such as emerald green or viridian, which no combination of blue and yellow printing ink, dye, or other pigment can properly reproduce. For the present, explanation and consideration of this vivid green as a primary colour in painting or printing must be deferred. Obviously, the phenomena connected with reflected light, as visually perceptible by daylight, of colours upon white paper, chiefly claim present attention, to the exclusion of considering phenomena concerning coloured projected light, or transmitted light as seen through coloured transparencies.

In the B.J. "Colour Supplement" of 1912, pages 43 and 55, I insisted upon the necessity of a fourth grey key printer, in conjunction with correct tri-colour impressions, for the production of good colour photographic prints. With seven years' increased experience, I am absolutely convinced of the truth of my contention. When contemplated under any aspect, nature conveys to the trained artist's visual sense a wonderful range of tones in grey, from pure white down to dense black, in combination with colour. It is this subtle union of greys with colour which form the substantial beauty of all real art work. No three colours alone, whatever the printing inks or colours may be, can adequately reproduce the true delicacy or powerful luminosities in subtle grey tones from light to dark, observable in nature, unless assisted by this fourth grey key printer.

Pardon reiteration. Probably all terrestrial material nature is wholly black-like in the absence of solar light, with the exception of phenomena connected with phosphorescence. This general black-like aspect of material things, when illuminated by daylight, will absorb in part, and repel in part, various colour portions of the light in accordance with the innate characteristics of the various things contemplated. The repelled colour parts of light are transmitted to our sight to constitute an actual colour impression of the thing seen; but invariably, in conjunction with colour, residues of the original black-like aspect of the material objects observed, changed by light into greys of various luminosities or tones, are also transmitted and received as visual impressions, assisting the effect of the light and shade in nature. The anatomical parts of the eye harmonise with my contention. Why are the nerve terminals of the retina, which receive all our visual perceptions of nature, made up as a fine delicate mosaic of two totally different nerve structures, known as rods and cones, unless for seeing nature in a combined dual manner? Moreover, in that excellent comprehensive text-book by G. L. Johnson, "Photography in Colours," 1914 edition, plate IV., page 51, a case is described and illustrated in colour of a paralytic patient, colour-blind in the left eye and of normal colour vision in the right eye, who made two colour drawings of the spectrum, viewed through a spectroscope, according to his visual perceptions by each eye. If we may judge correctly by the two facsimile coloured illustrations thus depicted, this patient reproduced the spectrum, by various shades of grey from white to black, quite devoid of any colour, as seen by the colour-blind left eye. This fact establishes a proof that the human eye is capable of perceiving a perfect monochrome grey visual impression of various light-luminosities, completely separate from any colour impression, where the anatomical structure of the eye for colour has been destroyed by paralysis. His reproduction of the spectrum, as seen by the normal colour-vision right eye, was quite correct in colour

according to human eyesight, establishing another proof that true mental impressions of vision depend upon perfect anatomical parts.

If the case for amending and supplementing tri-colour photography has been correctly stated, then the need is obvious for changing and adapting parts of apparatus in present use, according to suggestions made, particularly in reference to colour filters. A one-exposure camera, for the various negatives necessary in colour photography by the subtractive method of printing, is an essential requisite for proper production. If Mr. Butler can include a grey key negative printer, and also a special green printer with the ordinary tri-colour negative, made by his one-exposure camera, he would probably greatly assist proposed developments, as the negatives made by this camera are generally in true register.

E. G. HANDEL-LUCAS.

COLOUR SCREEN-PLATE HINTS.—Many photographers who have had but little experience with the screen-plate processes of colour photography complain of the lack of brilliancy of the colours in the deeper and more poorly lighted portions of the subject in the resulting transparency. The explanation of this is simple. The colours are not there in sufficient brilliancy in order for them to be properly rendered in the picture. In proof of this let us take a simple example. A laurel bush is viewed somewhat against the light. The best lighted portions of the bush will be found to be brilliant and strong in colour, but those receiving no direct sunlight will be found to lack colour. The colours exist we know, but they require a full and brilliant lighting in order to bring them into full prominence. As a general rule, against-the-light pictures are unsuccessful as colour subjects, as also are poorly lighted woodland subjects, and the photographer must realise that in order to get a good result an equal and uniform lighting is to be desired.

Too little attention is often paid by colour photographers working the screen-plate processes towards giving a correct exposure. In my own experience most of the failures with both the Autochrome and Paget processes may be traced to this cause. Exactitude, both in calculating with the aid of the meter and in timing the indicated exposure, is more essential in colour work than in any other branch of photography, since any error, even if only of a minor degree, is almost certain to falsify both the colour rendering and the contrasts of the final result. When calculating the exposure a meter should always be used that makes an actual test of the actinic value of the light, instead of a calculator, or table working upon certain factors, assessed for the most part by guesswork. Great care must also be taken to ensure that the meter is held in the proper way, in order to give an indication of the strength of the light that illuminates the *deepest* shadow parts of the subject. In colour work any trace of under-exposure, which would prove of little account in ordinary monotone work, and more especially in the case of rather dimly lit shadow detail, is to make the production of a perfect result impossible.

In the case of the Autochrome process, correct exposure is more essential than that of the Paget, since with the latter slight inaccuracies of the negative may be compensated for to a certain extent when making the transparency, though this plan is at the best a makeshift, and not to be recommended. With the former process under-exposure gives a very thin negative. Upon reversal the image is, as a rule, over dense, and it may be that the colours are falsified. On the contrary, over-exposure giving a dense negative, the positive may be too thin. Thus it will be seen that the secret of success is a carefully calculated exposure. Of course, there are modifications that may be employed in order to correct the results of under- or over-exposure, but their use does not produce the fine results that accrue from the course recommended above.

In the case of the Paget process, the plate upon which the negative is taken being a panchromatic the best results will only be obtained if the exposure is decidedly on the full side. We have found that any great under-exposure produces false colours; in fact, it is far better to over- than under-expose. When the subject contains extremes of contrast, as in the case of a woodland scene in sunlight, the only safe way is to expose fully for the shadows and to rely upon a careful development with a fairly dilute solution. A long experience of this process confirms my opinion that most of the failures met with by photographers may be traced to carelessness in giving the exposure.—R. M. FANSTONE.

ESSENTIAL FEATURES IN APPARATUS FOR COLOUR PHOTOGRAPHY By Robert		CORRESPONDENCE:—

THREE-COLOUR SENSITIVE UNITS FOR COLOUR PHOTOGRAPHY	43	NEWS AND NOTES	44

ESSENTIAL FEATURES IN APPARATUS FOR COLOUR PHOTOGRAPHY.

MANY beginners in colour photography are inclined to pay far too little attention to features desirable in their apparatus, and though the manufacturers of the materials used for various methods frequently state that any ordinary camera may be used, the process itself will be facilitated, and success assured if the photographer carefully examines his apparatus, with a view to its modification, if this is needed, according to the peculiarities of the particular process that he intends to work. I hope, by stating what is desirable in the way of apparatus, to forewarn the beginner against possible pitfalls, and also to assist the advanced worker who is not getting results as good as he desires.

With regard to the camera itself, I have found nothing so suitable as the ordinary field outfit, and its most desirable feature is rigidity. Exposures for colour photography, even under the most favourable conditions, are long, and if the outfit is not perfectly firm when set up, trouble on this score is a likely experience. I have found that a camera that has never given any trouble when employed for ordinary out-of-door work, gave badly blurred negatives when used for colour work in the deep shadow of the woodland, when the exposures were very long. Though most generally found upon the modern field camera, the swing-back and front is a great help in colour work by reason of the fact that they facilitate focussing without stopping down. The value of this will be seen later.

The hand camera, even when supported on a tripod, leaves much to be desired in the matter of rigidity, and considering that with all the modern colour processes the best result is only obtained with a full exposure, this is hardly in its favour. Of course, I do not mean to infer that good results cannot be obtained with any but a field camera, but merely as experience has shown me to indicate what is best. Snapshot exposures, with the camera held in the hand are impossible except under the most favourable conditions.

A shutter is not to be regarded as essential, and may even give trouble from vibration, if the exposures are very long. I always use the lens cap when the exposure, as it often does, runs into twelve seconds, or more, and find that this is superior for long periods to the best of shutters. In the case of roller-blind shutters, operated by a pneumatic release, reliance cannot be placed on the instrument remaining open for a long

period at "bulb," while if used at "time," trouble is apt to arise from vibration when pulling down the blind, to start the exposure; hence my preference for the cap.

While on the subject, it is perhaps as well to point out that the rigidity of the tripod should not be overlooked.

One of the most important points that should engage the attention of the colour photographer is, that his dark-slides should be suitable for the requirements of the particular process that he is working; but I have known many who have overlooked this altogether. Both the Autochrome and Paget processes differ very considerably in their requirements in the matter of dark-slides. With the former process, owing to the extreme delicacy of the surface of the plate (which is exposed glass-side towards the lens), no pressure of springs, or the separating plate of the double slide, may be permitted, or an abrasion of the film is certain to result. On the other hand, when working the Paget process, it is not only most important that there should be springs on the slide, but also that they do their work effectually, in bringing the negative plate into perfect and entirely uniform contact with the taking screen, in order that a perfect dot formation may be secured. Neglect of this, which allows of uneven contact between plate and screen, produces a transparency that is colour correct in portions only, and those working the process should pay every attention to this matter which is one upon which the success of the whole process mainly depends. I prefer, for both Autochrome and Paget colour work, double book-form dark-slides or the American block-form slide, in preference to the single metal pattern, by reason of the fact the double slide allows ample room for the plate. I have used the single metal slides for the Autochrome process, taking great care to prevent abrasions of the plate from the back of the slide. This must be quite free from dents, etc. The single metal slide is not, however, so well adapted for the Paget process, as it is a difficult business to get the two plates into the space only intended for one, unless the screen and plate are upon the specially thin glass issued by the makers for these slides, but even then there is some doubt about securing perfect contact. When carrying Autochromes in double dark-slides, I take out the metal separators and springs and load each slide with two plates, using the special cards

issued by the makers for this purpose, as separators. For the Paget process I use one plate in each slide, owing to the fact that if two exposures were loaded into each slide, the four plates would make a very tight fit when the springs are in position, and these would either tend to crack the plates, or to force the slide apart at the middle. I insert the screen and plate in the slide, taking note which shutter must be drawn for the exposure; upon the back of the plate is laid a piece of dead black card, and on this the springs; the slide is then gently closed, the springs forcing the plates into even contact. Speaking of springs reminds me to mention that the single central spring fitted to the centre of the metal slide divisions, is totally inadequate; my own are made from old pieces of clock-spring, covered with black velvet, in order to prevent their scratching. They are about two inches less in length than the width of the plate for a half-plate, are bent into a slightly concave shape, and placed in position in the slide with the ends resting upon the card separator. They should be about two inches from the top and bottom of the plate. These springs should not be too strong. On one occasion, I unthinkingly used a couple of springs from the back of an old quarter-plate printing frame; they forced the slide apart at the middle, and apart from fogging the particular plate, warped the slide very badly.

It is, perhaps, almost superfluous to add that everything inside the camera and slide should be perfectly dead black. This is far more important in colour work than in the ordinary branches of photography, since reflected light or halation may cause degradation of colour in the finished result.

That the lens is fully colour-corrected is of primary importance for all colour photography, and for this reason experience teaches me to favour one of the modern anastigmats in preference to one of the older R.R. pattern, since these may not be so carefully corrected of chromatic aberration. Another great advantage offered by the anastigmat is, that it will cover the plate sharply to the margins without stopping down, which may be necessary with an R.R. or other lens not having a flat field. Stopping down is to be avoided as much as possible, as this in practice tends to produce results that are devoid of the more subtle gradations. I am inclined for this reason to recommend a lens of fairly short focus for the plate in use, owing to the ease with which a subject in different planes may be focussed sharply at a large aperture. If, however, the photographer does not possess an anastigmat, an R.R. or good large-aperture portrait lens will serve. An important point is that the glasses of the lens itself must be free from any trace of discolouration. It sometimes happens that through the decay of the cementing compound, by reason of damp, improper storage, or other cause, the glasses of some lenses have a decidedly yellow or brown tint, which may upset the carefully adjusted lens-filter. I was once asked why a certain amateur photographer's colour transparencies lacked the brilliant colours that the process was capable of producing, and had instead a brownish tint. After some investigation, the cause was traced to the fact that the lens was a very old and discoloured instrument; indeed, sufficiently so to form quite a serviceable yellow filter, for orthochromatic plates. What has been said in this connection may be taken as applicable to all colour processes, especially to the Autochrome, and Paget, and perhaps in a slightly lesser degree to the making of colour-sensation negatives, for three-colour work. Lenses should never be stopped down below $f/16$.

We have heard little of colour photography with a telephoto lens, and I must confess to having little experience with it, but in the classes of work for which it is designed I can imagine no more valuable tool than one of the large-aperture telephoto lenses with a relatively short back focus such as the "Telecentric" or "Adon." The older telephoto lenses are

not so well suited for colour work, by reason of the fact that they work at a small aperture; while their definition, upon which much of the success of the picture depends, is very poor.

The soft-focus lens, owing to the reason that its particular feature is obtained by partial colour correction, is hardly a suitable tool for colour photography, but it is to be hoped that with the advance of the latter a lens of this type may be devised to give us some of the pictorial advantages that it now offers for monotone work.

Of course, only filters suited to the process, as issued by its manufacturer, should be employed. I have found that sometimes these vary in colour, but this will not affect their work, as they are carefully tested before sending out. Preferably, they should be mounted in optically flat glass, and every care taken of them. Experience teaches me that the best place for the filter is between the components of the lens, or if fitted in a cell, slipped over the back combination. There is a reason for this latter course. If the lens has not been perfectly colour-corrected, the filter may prevent any ill-effects from this, but if it were fitted to the front of the lens, such would not be possible. It is most important that no light is allowed to reach the plate, except through the filter, such as would happen if the latter fitted loosely, and this is one objection to the plan of using a thin circle of gelatine between the components of the lens, as it is almost impossible to obtain a perfect fit, and white, or other light reaching the plate other than through the filter causes the colour photograph to be of a blue, or violet tint. When using unmounted gelatine filters, I make a practice of cementing each between two circular pieces of thin black cardboard, with the centres removed, leaving about an eighth of an inch all round to act as a cell, the outer circumference of the cell fitting quite tightly into the lens mount. This also saves spoiling the filter through handling the gelatine surface with hot or damp fingers, which is frequently done. For the Autochrome process a special screen-holder is supplied to fit on the inside of the camera, which should always be used when the camera will permit. With the field camera there is always room on the inside of the front for this, but the compact folding pocket-camera does not always permit of this procedure. The solution of the difficulty lies in having the filter mounted in a well-fitting cell, to slip over the back combination of the lens.

An exposure meter is of great importance if waste is to be avoided and the production of perfect results is to be the rule, and not the exception. I recommend a meter that makes an actual light-test, in preference to one of the published tables, or calculating devices working upon a system of scales to be mentally adjusted by the photographer. Special colour-plate meters may be obtained, but there is really no need for these, though the Watkins Company supply an interchangeable colour dial for their "Bee" meter. This is a great help, and simplifies matters considerably.

Of our old friend, much abused and ill-esteemed, that most of us still cling to—the dark-room lamp, though it may be fitted with a "safe light," I would point out that no light is "safe" for colour plates, and the lamp should be simply used as a means of seeing what is wanted in the room, and in aiding the photographer's sense of touch, and not for the purpose of peering at the developing-plate in its early stages. I use several thicknesses of the safe-light paper issued by the makers of the particular plates that I happen to be working, cemented between two pieces of plain glass with a solution of Canada balsam, and bound up with lantern-slide binding-strips. This fits into the dark-room lamp in place of the usual screen. It is to be noted that for powerful illuminants a greater number of sheets must be used than may with safety be employed with a candle.

ROBERT M. FANSTONE.

THREE-COLOUR SENSITIVE UNITS FOR COLOUR PHOTOGRAPHY

[The idea of producing a sensitive material all ready for use in the making of colour photographs is one which evidently still occupies the minds of inventors. Although it may be thought unlikely that anything more practical for the purpose than Mr. Ives's Hiblock system is likely to be devised. A Danish experimenter, Jens Herman Christensen, whose name is associated with other inventions in colour photography, has recently been granted a patent for a system of this kind. For the sake of completeness in our records of the introductions we give below extracts from the patent specification, No. 128,781, although it is by no means sufficiently clear to us as to precisely how a three-colour composite photograph is produced according to the directions given.—EDS. "Colour Photography" Supplement.]

The invention provides a process of producing a coloured picture by sticking together two supports carrying three coloured films which have been produced by exposure of selective colour sensitive films followed by development, and the images coloured, one of the supports carrying two of three films constituting the parts of the picture, and the other carrying the third film; and the method consists in mounting before exposure at least one of the two supports in a frame, where it remains during chemical treatment and drying, and from which it is removed only after having been stuck to the other support. In some cases the frame can be retained after the supports are stuck together so as to form a frame for the picture. In such a case the coated support and the frame are supplied as a unit by the manufacturer.

The object of using such frames is to prevent the supports and films from contracting or from being displaced during the various steps of the process, and to secure an automatic and complete registering of the images.

Two frames can be used, for example, in the following manner:—

A support consisting of a thin collodion film is coated on one side with a film of collodio-bromide and collodio-chloride emulsion with good contrasts and containing a yellow screen dye (for instance, so-called filter-yellow), and on the other side with a green-sensitive emulsion which may contain a red screen-dye. A second support consisting of a piece of paper is provided on one side with a red-sensitive emulsion.

In the drawings the double frame shown in Figs. 1 and 2 comprises frame-pieces *a* and *c* connected by hinges *b*, and secured when

Fig. 1.

Fig. 2.

closed by a clip *f*, or some other suitable means. The frame-piece *c* has a protruding part or edge *e* as shown, and both of the frame-pieces have holes *d* for registering pins.

The double frame shown in Figs. 3 and 4 comprises two flat frame-pieces *g* and *h*, connected by hinges *k* and secured in the closed position by a clip *o*. The edge *e* protrudes from the frame *c* at least as far as the thickness of the frame-pieces *a* and *g*. The frame-piece *g* has holes *m*, and the frame-piece *h* registering pins *n*, as shown. The sides of the frame-piece *h* are preferably somewhat broader than those of the frame-piece *g*.

When the process is to be carried out, the paper *p*, Fig. 5, is fixed between the parts of the frame shown in Figs. 1 and 2 so that it is stretched over the edge *e* and with the coated side upwards, and the edges of the paper are squeezed between the frame-pieces.

The collodion film *q*, Fig. 5, coated on both sides, is held flat between the frame-pieces *g* and *h*, the yellow film being turned towards the frame-piece *h*. These operations must be done under a ruby light, and in some cases in darkness. The two double frames are now laid together, the pins *n* being registered in the holes *d* so that the two films are in close contact, as illustrated in Fig. 5. The exposure can now be effected either in a camera or by contact printing with a coloured picture, which is laid on the film *q* in the frame-piece *h*. After the exposure the two frames are separated and the films are developed and treated further while supported in their frames. The pictures may, for example, be converted into silver-iodide prints and coloured with suitable dyes. The frame-pieces *g* and *h* in connection with the film form flat trays into which the solution of the dye can be poured, one side being coloured at a time, each with its own dye. The frame with the film may also be arranged as a partition in a suitable container, and both sides may be coloured at the same time. After colouring, and in some cases fixation and washing out of the films, they are dried, always remaining in their frames, and after drying the paper is provided on its image-bearing side with adhesive and the film is applied thereto, the frames being put together again as shown in Fig. 5, and the film and paper pressed together. As an adhesive, glycerine or other substance which will not soften the films may be used.

If the paper used has a considerable thickness it may be necessary in order to facilitate the mounting in the frame to cut off the corners, and by folding the edges to impart to it folds or bends corresponding to the size of the frame.

Fig. 3.

Fig. 4.

Fig. 5.

If it is desired to produce a transparent coloured picture the paper must be replaced by a glass or celluloid plate, which in most cases need not be mounted in a frame. In such a case a single double frame only is used, in which the film coated on both sides is mounted. The glass or celluloid plate must then have holes corresponding to the registering pins on the frame.

In the case of an opaque white glass or celluloid-plate being used, a picture is obtained which may be viewed in reflected light in the same manner as a picture on paper.

COLOUR WORK is among the branches of photography to which special attention is to be paid by the recently formed "Scientific and Technical Group" of the Royal Photographic Society.

THREE-COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—Mr. Handel Lucas's letter in the "B.J." of October 5, in reply to Mr. Yerbury's query, "Is Three-Colour a Blind Alley?" seems to tend only to thicken the haze which envelops this subject in the minds of even many experienced workers. I gather that Mr. Lucas is a process engraver, and as a member of the same interesting craft, I should like to state that while I have found all the faults in tri-colour work that he indicates, I have not found that they are in any way inconsistent with, or unexplained by, the scientific theory. Indeed, I find that it is only by referring to, and being guided by, that theory that these faults can be kept within limits.

The first point Mr. Lucas disputes is that the inks are the chief cause of faulty results, and refers to chromo-lithography to support his contention. I would like Mr. Lucas to take his most successful pre-war set of colour blocks, and re-prove them in the very best match he can get in inks now, or, if he repeats his statement to any good colour printer who is engaged in reprinting a sheet of pre-war colour plates, he will receive as direct and forcible a reply as he could desire. The reference to the results obtained by chromo-lithography has no point in this connection, for the "twelve to twenty various coloured ink impressions" he mentions are almost all light tints, and are very far removed from the very intense yet transparent inks required for printing three-colour. If Mr. Lucas wishes to see how the use of tints can improve tri-colour results (still quite along the theoretical lines) let him study some examples of American off-set work, such as the cover of the "Metropolitan Magazine."

Passing over Mr. Lucas's extraordinary statement, that emerald green is the one colour which cannot be produced in printing by some combination of red, blue and yellow, I come to his main point, which is a recommendation of a fourth plate printed in grey. Of the practical value of the grey printing I am very well aware, but I find it is required to make practical results attainable commercially, not because of any failure of the theory.

It would occupy too much space to go into the true use and advantages of the grey plate and the use of lighter colours, but this might be done at some future date, if the editor permits.

Nor do I propose to follow Mr. Lucas in his adventures amongst anatomical and psychological detail, beyond remarking that he is leaving what has yet to be proved other than solid ground for a region but vaguely mapped. It is very clear and comforting to study illustrations in text books, and talk about the "fine, delicate mosaic" of "rods and cones," but get the very best and clearest prepared section of the retina and compare it under the microscope with the convincing text-book figure and you will feel much less certain.

In conclusion, I would like to thank Mr. Yerbury and Mr. Lucas for opening the subject, and would point out that Mr. Lucas's demand on Mr. Butler means not only a grey plate (which has been made—without handwork—by Dr. Albert, and also by Mr. Gamble, of N.Z., though in both cases hardly practicable commercially), but also a means of preventing the grey parts from being recorded in the colour plates.

9, Albany Street, Edinburgh.

WILLIAM B. HISLOP.

News and Notes.

THE GORSKY COLOUR PROCESS.—Some further particulars are given in the "Daily News" of November 4 last regarding the process of colour photography said to have been invented by Dr. S. M. Prokudin-Gorsky.

It is claimed that all the difficulties of colour photography have been overcome. One of the chief problems was to make the process capable of snap-shot as well as "time" work. This problem has

been solved, and the exposure can be as rapid as with the ordinary emulsion—thus fitting the invention for cinema work.

It is claimed also that the amateur photographer will merely have to provide himself with a special camera designed for colour work and plates or films covered with a secret emulsion. After exposing in the ordinary way he will then have to reconcile himself to developing with three separate solutions, and printing will be rather more complicated than with the usual paper, but he is promised a result which will reproduce natural colours without any of the crudity of some colour processes.

The invention is in the hands of the Cinema Artists' Association, of Holland Park, who intend to develop it on an estate which they have bought at Byfleet and fitted with laboratories and studios. The cost of a colour film is expected to be only 15 to 20 per cent. higher than that of the ordinary black and white type. The special camera and plates will be put on the market.

REGISTERING PAGET TRANSPARENCIES.—Many novices, in endeavouring to register transparency and screen the first time or two scratch both before registration is obtained, and as this defect is one that it is quite impossible to cure, prevention is necessary. The surfaces of the transparency plate and of the screen are delicate, and there must be no dust between the two, and any roughness or dried-on particles of the films at the edges of the transparency should be carefully shaved off with a sharp knife or old safety razor blade. If they become detached during registration and get in between the two plates they may prevent perfect contact or cause scratches or abrasions. Mention should be made of the fact that it is the viewing screen that should be adjusted on the film of the transparency plate, and if care is not taken both films will be rubbing against each other, with the same result. One other point should be emphasised. When registering the viewing screen and plate should be held in exact line with the operator's eyes, for if held at an angle the picture may appear correct, but in reality, if viewed squarely, or in the case of a slide projected on the screen, false colours will be in evidence. After registration we attach three letter clips to the slide or transparency, and cement the two plates along all four edges with fish glue or other adhesive before commencing to bind them up, putting the plates aside with the clips still on, for the glue to get thoroughly dry before binding up. In this way there is no fear of losing the register during this operation, as often happens if this precaution is not taken.—R. M. F.

PAGET COLOUR PHOTOGRAPHY.—It is questionable whether those who practise this method of colour photography always obtain the beautiful results that this process is capable of giving. I therefore give a few hints from my own practise which may be useful. It is impossible to mask these transparencies in the ordinary, but the following is even better. Fixed-out lantern plates are taken and borders of different dimensions are drawn round with blocking-out compound. These are used to make negatives, consisting of an absolutely opaque centre. After a lantern plate has been exposed under the picture negative, one of these transparent border negatives is registered and a second exposure made. The transparency on development therefore has a black edging. I have also found difficulty occasionally in registering the transparency, although the negative on test is correct. This is due to bending of the negative when printed in an ordinary pattern frame. The cure for this is the type of pressure frame used by process workers. This is preferable in every way, as it is a guarantee that the little pattern on the negative is sharply reproduced. In fact, it is used for an almost similar reason by process engravers. I have also optically sealed a transparency and its screen together with Canada balsam, but the result was rather disappointing. Certainly parallax was reduced, but the result was no more brilliant than an unsealed picture. To those who wish to obtain the most perfect result regardless of time and money, I can recommend replacing a single exposure through the orange compensating filter by a triple exposure through the usual trichromatic set of filters. As soon as I have an opportunity I am trying a landscape by the above method, but replacing the red filter by a Wratten F (deep red) to produce a really artistic sky. I think the Paget Co. deserve an enormous amount of credit for keeping their process on the market during the war. I trust they will reap the reward now. I also hope they will persuade the camera makers to give us better dark slides. The ordinary book-form is not so bad, but still a lot of improvement is possible.—H. E. R.

LANTERN-SLIDES BY THE SCREEN-PLATE PROCESSES. By R. M. Farnstone	PAGE 45	CELLULOSE ESTER CUM COLLOID TWO-COLOUR SCREEN FILMS	PAGE 46
--	------------	---	------------

LANTERN - SLIDES BY THE SCREEN-PLATE PROCESSES.

In common with other branches of photography, there is no better means of exhibiting the fine qualities of good work than by projection of the image in natural colours upon the lantern screen. The ordinary transparency is, of course, not quite satisfactory when viewed in the hand, and every colour photographer is not in a position to instal an elaborate appliance for viewing. We are all of us familiar with the person who will persist in holding our favourite transparency in a position from which it is impossible to view it to the fullest advantage, and also, I think, have grown rather tired of answering the oft-repeated question, "When are you going to print it on paper?" The lantern-slide is, then, the solution of many problems. Among its advantages I may, perhaps, mention the following. It is economical, for, apart from the initial outlay, any number of duplicate lantern-slides by the Paget process may be produced for about one shilling each. The image is seen upon the screen without any difficulty, and gains to a marked degree by projection. A larger picture is shown than can be got in a transparency, and all its more subtle graduations of colour, which would be lost in an ordinary transparency, can be fully appreciated. It seems a pity, to my mind, that the lantern-slide in its best form, such as produced by the Autochrome and Paget processes, is to a great extent neglected. Such results as these offer are far in advance of the crudely coloured hand-painted lantern-slides in vogue years ago, and still widely employed. I was present some time ago at a lecture intended to set forth the delights and attractions of a certain colony. Some of the slides were monochrome, and the others obviously hand-coloured. All were more or less disappointing when compared with what colour photography would have done at its best. There is, I think and hope, a great future for the commercial lantern-slide, and perhaps some notes on lantern-slides by the screen-plate processes may prove helpful at the present time, and may also serve to induce those who may be turning their attention to colour photography to present their work in this way.

The preliminaries for colour photography, whether the results are to be exhibited as transparencies or slides, are much the same, except that with the latter a greater degree of technical perfection is demanded. I have seen slides that looked quite satisfactory when viewed in the hand as transparencies appear very indifferent when projected on a lantern screen, simply by reason of the fact that they possessed certain technical im-

perfections previously not observed. A sharp focus over practically the whole picture is usually required when slides are to be made, and for this reason a lens of fairly large aperture and short focal length is ideal, since stopping down is to be avoided as much as possible. Most of my own work is done by the Paget process with a $3\frac{1}{2}$ by $2\frac{1}{2}$ camera, using a lens of about $3\frac{1}{2}$ ins. focal length, working at $f/7.7$. This gives a general all-over sharpness at its full aperture, and rarely has to be stopped down further than $f/11$. It is most important that every shade and graduation of colour is properly rendered, or the best results will not be obtained. Care must also be taken with the Paget process to avoid slight degradations of colour in certain areas of the picture. These may easily pass unnoticed in a transparency held in the hand, but are apt to assert themselves to a greater degree on a large projected image. A well-backed negative plate will do much to avoid this, according to my own experience, and backing should always be done when making negatives for slide work.

A great deal of the success or failure of a colour slide will depend upon its density. It will be found with the Paget process a perfect negative is the finest possible foundation for a successful result. It is often assumed that if the negative is not quite as good as it should be, a good result may be obtained by a modification of the exposure and development when making the transparency. This, however, tends to upset the contrast and intensity of colour of a slide. Generally speaking, a lantern-slide in colour should be just a trifle more dense than a good monochrome slide, but it must be remembered that if the density is overdone, too great intensities of colour will be in evidence. If, however, the negative in the first instance has been correctly exposed—by this I mean it is better to err upon the full side, followed by correct development—there is little fear of falsification of colours. Too great a density may also bring into evidence slight effects of degradation of colours in the form of a faint halo where a strongly-lighted colour comes against the sky or another area of colour less well lighted. This effect may not be noticeable where there is less density in the plate. Autochromes intended for slides call for little special mention in this respect, as the procedure for a perfect Autochrome transparency is also identical for the production of perfect slides. The secret of success lies in giving a correct exposure to the plate in the first instance.

When transparencies by the Paget process are registered

with the object of their being viewed in the hand, it sometimes happens that by reason of the fact that the photographer held the transparency slightly at an angle, it is necessary to hold the plate slightly out of parallel with the eyes when viewing, to see the correct colours. This, in the case of an ordinary transparency, if only in evidence to a slight degree, is not a matter of any great moment, since adjustment is semi-automatic, but with lantern-slides there must be an entire absence of parallax if the projected image on the screen is to be correct. The photographer when registering must keep the two plates absolutely parallel in every direction with his eyes. If any difficulty is experienced in this direction it is an easy matter to construct a simple device that will ensure correct registration. A box should be constructed of about 2 ft. in length and of dimensions to take the slide at one end, with a means of holding the same. The other end of the box may be closed, save at the centre, where a hole is made, circular in shape, of about $\frac{3}{4}$ of an inch in diameter. The slide, after being registered with its viewing screen, is tightly held together with three or more "bull-dog" letter clips, and placed securely at its end of the box. Then if the photographer looks through the viewing hole, and keeps his eye close thereto, a glance will tell if a perfectly parallel registration has been made, the object of the box being to prevent any possibility of viewing the slide from an angle. The principle is something the same as that of a direct vision view-finder. Many photographers should be able to dispense with such a device, and it must not be thought that getting a perfectly parallel registration is a matter of great difficulty, since this is by no means

the case. This point is an important one, and may seem obvious enough, but it is one that I know has often been overlooked until the slides were fully bound up and projected. Fortunately, if a slightly incorrect registration has been made, it is an easy matter to do the work again more carefully and correct the defect.

It is not possible to interpose a mask between the two plates in the case of the Paget process, as is generally done with monochrome slides, for this prevents perfect contact, making satisfactory registration impossible. This leaves but one position for the mask—i.e., on the outside of the cover-glass, which is really the viewing-screen. I have seen slides masked by painting round the desired portions of the picture with a fixed Indian-ink, but this is not a very satisfactory method, and demands a certain skill in brushwork, to enable the job to be done properly. My own plan is to attach a built-up mask composed of strips of lantern-slide binder to the outside of the glass, and then to bind the slide again, in order to assist holding the masking strips; also this method lengthens the life of the binding. There is, of course, no objection to inserting a mask between an Autochrome slide and its cover-glass, and this, without doubt, is the best possible place for it. When the picture fills the slide there is no need to mask the plate if properly bound. Speaking of binding reminds me that the linen binding strips give far more satisfactory wear than do the ordinary paper ones, and are well worth the extra cost. They should always be employed with slides intended for constant use, commercial work, lectures, etc.

R. M. FANSTONE.

CELLULOSE ESTER CUM COLLOID TWO-COLOUR SCREEN FILMS.

[Technical details are given in a recent patent specification, No. 129,717, of Mr. J. T. Smith, of a process of preparing mosaic two-colour film and films of a degree of fineness which, it is claimed, is sufficient for the production of colour films for cinematograph projection. The following are the chief working details disclosed in the specification. In using the word "antichromatic" the patentee explains that he employs it in the sense in which it is used by Chevreul in the latter's "Laws of Contrast of Colour"—that is to say, in the meaning of "approximately complementary."—EDS. "B.J."]

The means by which a colour-screen base can be produced is, in general terms, as follows:—

(a) A surface of cellulose ester, or salt, as nitrate or acetate of cellulose is coated with small distributed areas of a fluid aqueous colloid preparation containing a transparent colour.

(b) The colloid areas if not already insoluble in cold water are, when necessary, or when an aqueous fluid is to be brought into contact therewith, insolubilised to water and the whole is thoroughly dried.

(c) The surface is treated for a short time with a solution of a colour approximately complementary or anti-chromatic to the tint or colour of the colloid preparation, the solvent being one which softens the cellulose ester but not the water-soluble colloid, which now forms a resist.

(d) Excess colour is blotted off or otherwise removed. Operations *c* and *d* may be repeated to obtain a right intensity of colour.

(e) The surface is treated with an appropriate fluid to remove traces of the second colour which adhere mechanically to the surface of the colloid areas; soured or acidulated water being generally appropriate when the solvent of the second colour is a fluid base, as aniline, for example.

(f) If at this stage either colour requires intensification to realise the requisite total general, or average, approximation to neutral tint, an aqueous solution of dye may be applied to colour the colloid further, or, alternatively, a stain appropriate to affect the cellulose ester may be applied. In the latter case, operation (e) may require to be repeated.

(g) The colour base, as produced at stage (f), will serve, when but two colours are required, the two colours being green and red or near variants. A third colour, blue, may now be added

by cross ruling, random spraying, printing, or otherwise; this third colour being arranged to take or bite on one or both of the colours previously produced.

(h) The composite colour screen base may now be covered with a protective waterproof stratum, if required, and is ready for coating with sensitive emulsion. To isolate the colouring more completely from the emulsion the film of cellulose ester which carries the composite colour screen system may be stripped from its support, or a thickness of cemented colour-face downwards on any convenient support, or a thickness of cellulose resist may be built up on the screen as here described.

(a) Although ordinary celluloid or acetate celluloid may be used, the presence of additions, as, for example, camphor in indeterminate quantity and quality (degree of purification from the accompanying oil) may disturb operations, so, when practicable, the applicant prefers in the case of the finest screens to use a cellulose ester or a mixture of esters without the addition of camphor or other solid solvent. A somewhat stiff amylic-acetate colloidion poured on a levelled glass slab forms a desirable base for operation, and a convenient method of retaining the film of ester on the glass is to lay an edging of indiarubber on the margin of the face of the plate which is to be coated, as by painting an edging on the face of the glass with the official "liquor caoutchouc" or indiarubber solution of the 1893 edition of British Pharmacopœia. Otherwise the whole surface of the glass plate may be rubbered, and in this case the purest benzene without any sulphur compound may be desirable. The stratum of cellulose ester being thus obtained and conveniently supported on a level and rigid support of glass, the surface is then plotted out or partly covered as a lined or stippled system, with a colloid material charged with a suitable soluble colour, the colour

being red or reddish when the second colour for staining the ester is green or greenish. On the other hand, the colour in the colloid mixture may be green or greenish, in which case the second colour for staining the bare parts of the ester should be red or reddish.

The quality of the pyroxyline used for this purpose is a matter of some importance. The official "pyroxyline," prepared according to the official instructions on page 323 of the 1914 edition of the British Pharmacopœia, is quite satisfactory, but most samples of tough or "low temperature" nitro-cottons of commerce, or "surgical" pyroxylines may serve. Perfect solubility and toughness are the leading criteria.

Pyroxyline as specified	100 grs.
Amyl acetate	4 fl. ozs.

About 100 grains of this colloid or solution may be used as the dose for coating a quarter-plate (3½ by 4½ ins.), this giving a desirable thinness of film when the finest lines or grains are to be formed, whereby obviously lateral penetration or diffusion of the stain under the colloid lines is so minimized as not to injure or darken the colour combination by overlap of colour.

COLLOID MIXTURE OR INK FOR LINES OR GRANULATION.

RED.

Para-rosaniline colour-base	12 grs.
Water	240 grs.
Glacial acetic acid	10 grs.

When all is dissolved add:—

Fish glue	140 grs.
-----------------	----------

Excess of acetic acid should be avoided, as also the use of fish glue, which is acid, as acidity of the mixture may cause the aniline solution (or like solution) of green dye to adhere to the lines.

Para-rosaniline colour-base (as distinguished from para-rosaniline leuco-base) is regarded by chemists as tri-amino-phenyl-carbinol, and applicant believes that this is the colour base of the dye known in commerce as "diamond magenta." To be specially appropriate for use in relation to the invention the para-rosaniline colour base should be free from phenyl or alkyl substitution products which give a bluish cast to the colour. An ordinary rosaniline base or similar base may be used, but in preparing the colour the crimson cast should be preferred. Crimson colours of the nature of magenta are well known to experts in aniline colours.

The fish glue used is the semi-fluid kind sold commercially as "Le Page's special photo-engraving glue for process work." This is understood to be guaranteed as free from acid.

GREEN COLLOID SOLUTION.

"Acid green colour" of commerce	10 grs.
Water	55 grs.

Add the following mixture:—

Fish glue (as noted above)	40 grs.
Water	50 grs.

Any undue acidity should be avoided, as in the case of the red colloid mixture and all such mixtures. The colloid inks for the purpose of the invention may be coloured to suit whatever colour combination is selected for the composite colour screen, the selection being according to well-known principles. The colour must, however, be soluble in water.

Alternatively, the colloid mixture may be uncoloured, and after the lines or areas are insolubilised they may be coloured by the use of an aqueous solution of dye, as explained below.

(b) To insolubilise the fish glue ruling, the ruled plate is by preference exposed to the vapour of formaldehyde, conveniently from an aqueous solution of formaldehyde; another method is to add a soluble chromate to the ruling ink or mixture, and to allow time or light, or both, to bring about insolubility of the dry lines.

Insolubilisation of fish glue areas in a vapour bath of formaldehyde has been touched upon, but, if desired, the formaldehyde vapour bath may be used for a supplementary hardening: alternatively a formaldehyde liquid bath may be used for any colloid areas or lines which are not immediately soluble in cold water. For the first stage in insolubilising the areas of unchromated fish glue, the formaldehyde vapour is of great value, as it in no sense or degree impairs the sharpness or perfection of the marginal parts of the areas.

After insolubilisation, and before the next stage (c), the gelatinous areas should be thoroughly desiccated, this being conveniently done by slight warmth or by leaving the surface for a time in a cold drying box containing chloride of calcium.

(c) The solvent of the staining fluid should be of such a nature as to penetrate, soften, or incipiently dissolve the bare surface of the cellulose ester, but not so active as to attack or soften the colloid areas in any way, in the sense of making the base so pasty or soft as to bring about removal of the lines or areas of resist material.

Ordinary alcohol, methyl alcohol, and acetone as such, and, while anhydrous, fulfil the above conditions, but as in drying or evaporating these solvents absorb moisture, their use often or generally involves a slight subversive staining of the colloid areas, the aqueous residue drifting over to the colloid resist and staining it.

A solution of aniline colour in aniline itself is well known as an ink for writing on celluloid, and is especially suitable, as the surface of the colloid areas is not stained or attacked, provided that the herein stated precautions are observed.

Solutions suitable for the purpose of the invention are as follows:—

1. Aniline of the grade sold commercially as "analytical reagent" or A.R. 100 grs.
"Acid green" aniline colour 12 grs.
2. Aniline, as above 100 grs.
"Methyl red" aniline colour 4 grs.

The plate bearing the stratum of cellulose ester, on which are greenish or reddish lines of colloid, as described, having been well desiccated, is quickly and uniformly brushed, or mopped, or soft-rolled over with the green or the red dye dissolved in aniline, the green solution being used if the colloid lines are red, and the red solution being used if the colloid lines are green.

(d) After a short interval, 3 to 30 seconds, for example, the excess is blotted off with a short pad, and, if necessary, other similar applications and blottings off follow. By several short treatments, as contrasted with one prolonged action, the tendency of the dye to penetrate laterally or obliquely under the colloid lines is diminished. The adjustment of the activeness of the solvent in relation to the quality of the base of ester or celluloid is an important aspect of the invention. As above stated, the purer aniline sold as "analytical reagent" is the preferred solvent in such a case one procedure is first slightly to soften the surface of film consisting of the pure cellulose ester (cellulose nitrate) as deposited from the solution in amyl acetate. This purer aniline is also suitable for many, or perhaps most qualities of commercial celluloid film, but the applicant has met with qualities so resistant to the action of pure aniline as a solvent that endeavours to stain the material with the aniline solutions given above were futile. In such a case one procedure is first slightly to soften the surface of the celluloid with methyl alcohol, amyl acetate, or acetone, and then to apply the solution of dye in aniline. Alternatively, the above-mentioned solvents may be mixed with the aniline solution of the dye.

In the case of a quality of celluloid which is extremely resistant to solvents, nitrobenzene may be used in a similar way to increase the solvency of the aniline. In an extreme case the staining dye may be dissolved in the pure nitrobenzene, but in all ordinary cases the solvent or softening powers of such a solution would be excessive.

In the use of nitrobenzene, especially by itself, there may be some care required in selecting a suitable colour, but the inventor found malachite green to dissolve readily in a sample of nitrobenzene which he had purified to the utmost. This solution kept well for a few weeks, and instantly stained the hardest celluloid of the applicant's selection.

(e) It is now generally expedient to remove the excess of aniline by soaking the plate in weak sulphuric acid for about four minutes; one weight unit of sulphuric acid to from 20 to 100 weight units of water being convenient. The plate is now washed and dried. This treatment in the acid bath also tends to remove any trace of the aniline mixture which may adhere to the surface of the colloid resist. Other rinsings appropriate to the stain and its menstrum may be used.

(f) To intensify the colloid areas, an aqueous solution of an aniline dye should be used, and the plate should be thoroughly dry in order that the film of ester may become hard and compact, so as not to take colour readily from an aqueous solution. That the pyroxyline or ester should be of the tough kind rather than pulverulent or soft kind is sufficiently indicated above. In intensifying the stain on the cellulose ester surface, care should also be taken that the plate is completely dry. The process of intensification is merely another operation as detailed under the heading. By using a suitable dye, tint (as also intensity) may be modified by the intensification.

(g) The instructions so far serve to produce a composite colour screen in two colours, the third colour, if required, being added afterwards, either as an independent blue ruling, lining, or spraying, which impartially takes upon both elements of the two-colour screen, or, alternatively, the blue colour may be made discriminative in the following manner:—

Let it be supposed that the green areas are produced in the film of cellulose ester and that the red colour is embodied in the colloid areas. If now a solution of aniline blue in aniline, or its technical equivalent, as herein indicated, is ruled or sprayed, and, after blotting off, the plate is treated in the above-mentioned searing bath, the blue colour will take only on the green where it will be especially required, and will not take on the colloid surface charged with red. Alternatively, if the colloid lines are green, an aqueous solution of blue dye, with or without the addition of a water-soluble colloid, may be sprayed or ruled as a scattering over the whole surface, and on rinsing off with water the blue will leave its impress most notably or entirely on the green colloid lines. The tints or colours involved in this kind of discriminative treatment may be varied according to the requirements of the colour scheme.

When the blue is to cross the green, or partly cover the green, an original green of a yellower tint is indicated than when the green is to form part of a two-colour system; on the other hand, when the greenish colour of the two-colour system is a greenish blue (alternatively a bluish green), the third colour applied in any of the above modes (discriminative or general) may be yellow, instead of blue, as specified. In this case the yellow over the greenish-blue gives green by abstraction or obstruction, leaving the uncovered portions of the greenish blue to form another element of the combination.

(h) An especially expedient course when flexible surfaces or "films" are required for exposure in the camera is to strip the composite colour screen as prepared on a glass support and to mount the stripped composite colour screen ester side upwards, on ordinary celluloid, this giving an inert or non-active side for coating with the sensitive emulsion. For this purpose the receiving surface of celluloid should be made slightly adhesive as by a thin coating of amyl acetate collodion, and the stripped composite colour screen is pressed, colour side downwards, into close contact and adhesion. In this operation the least practicable quantity of adhesive should be used, so as to minimise any interdiffusion or overlap of colour. Heat may be employed with the pressure, or alternatively heat and pressure may be employed without any adhesive. Instead of applying adhesive as such, the celluloid or ester surface may be moistened or fumed with a solvent, as, for example, amyl acetate.

Successive thin coatings of celluloid varnish or cellulose ester varnish, prepared, for example, with amyl acetate as a solvent as hereinabove specified, may now be applied, thorough drying being effected between the applications. Thus is built up any required thickness of inert protective material between the composite colour screen and the emulsion, or the composite colour screen and any chemical used in after-treatment. The reason for using successive thin coatings is to prevent such softening of the whole mass as may lead to subversive inter-diffusion of the colours, and, if desirable, a thin stratum of indiarubber or resinous material may be used between any two coatings. The operation of transfer makes it practicable to thicken the back or the front of the original film of cellulose ester, but where no transfer is made the indiarubber substratum may conveniently cover the whole surface of the glass plate instead of being confined to the edges.

Although aniline is mentioned as a desirable solvent for such colour as is used to stain the cellulose ester, other solvents may be

used, the whole range of what may be vaguely termed alcoholic, ethereal or aromatic solvents being more or less available, and the solvent must be selected in reference to the colouring body used. Preference is, however, given to basic solvents which are physically and chemically comparable to aniline, removal in an acid bath being easy; and in this connection may be mentioned the liquid toluidines (ortho-toluidine and meta-toluidine), whether alone or with aniline.

It should be understood that the composite colour-screen produced as herein described, by interdependent colouring and staining in stages, may be formed on ordinary thin celluloid or on similar sheets of cellulose ester without camphor, either after manufacture or while the celluloid is with or on the moulding plate or moulding wheel, and emulsion may be laid on either side of the stripped sheet as may be expedient.

In all heliochromic processes it may be expedient to introduce a neutral key element to conduce to critical sharpness and also intensity. One way in which a neutral key can be associated with results by the present process is to superimpose a weak monochrome taken actually from the same standpoint, any suitable or known optical device being used for this purpose. Another mode suited for cinematograph projection is to produce alternately heliochromes, by the herein described process, and monochromes on the same film, a lens of higher or deeper defining power being preferably used for the monochrome alternations. In the final or exhibition film the heliochromes and weak monochromes would be cast on the screen in alternation.

A DYE-IMAGE COLOUR PROCESS.—Particulars are given in the "Patent Journal" of the process of J. H. Christensen (patent No. 133,034), now open for inspection under the International Convention. For producing dyed images, advantage is taken of the catalytic effect of the finely-divided silver of an image on the action of reducing agents on certain dyes. A bromide plate is dyed with oxaminerosa, exposed, developed, fixed, and then treated with a powerful reducing agent, such as sodium hydrosulphite or stannous chloride, which has the effect of bleaching the dye where the silver is deposited. The silver is subsequently removed by chromic acid or Farmer's reducer, leaving a clear colour picture. Alternatively, the development and bleaching can be effected simultaneously by treating an exposed plate in a bath containing sodium hydrosulphite and potassium bromide, the silver and any silver bromide being subsequently removed by Farmer's reducer. Alternative dyes of the dianile class are given, some of which—for example, Chicago blue—require to be subsequently mordanted. Toned silver images can be treated similarly.

THE PROKUDIN-GORSKY COLOUR PROCESS.—Technical particulars of this process, which has been the subject of news paragraphs in the daily Press, are now ascertainable in this country from the series of patent specifications which have been filed at the Patent Office under International Convention, and, under that Convention, are open to public inspection before acceptance. These specifications are as follows:—

- 18,585.—Production of coloured diapositives. November 9, 1918. 135,161.
- 23,437.—Apparatus for the treatment of articles such as photographic negatives with liquid. November, 9, 1918. 135,165.
- 23,718.—Printing apparatus for the production of diapositives. November 9, 1918. 135,166.
- 23,933.—Apparatus for closing of a circuit for a certain period. November 9, 1918. 135,167.
- 24,336.—Photographic camera for taking part negatives for pictures in natural colours. November 9, 1918. 135,169.
- 24,982.—Apparatus for the production of coloured cinematograph films. November 9, 1918 135,171.

In each case the number first given is that for the year 1919 allotted to the specification during its passage through the Patent Office. The number following the title of the patent is the serial number according to the system introduced a few years ago. The date in each case is that claimed under the International Convention, being the date of the first foreign application.
